Such considerations go to show the futility of *ad hoc* dietary surveys in this sphere. The fallacy involved in applying statistical laws to individual cases requires no emphasis. In the present instance the application of a national, average, "per caput" cost figure for a dietary to a certain social class or to individual cases from families of varying family composition is entirely without warrant; the climax is reached when it is applied to cases where such psychological factors as "ignorance" and "luxury-purchase" are in evidence. The situation is an individualistic and intensely personal one to which statistical methods are inapplicable. A "locality" factor (reflecting to a considerable degree middleman's costs and profits) is also involved, for owing to varying costs in different districts (vide Dr. Neustatter's price table for

Bermondsey) no general or national average figure for the cost of a dietary in any one social class can be applied to this same class in a district or subdistrict chosen at random.

The only justifiable procedure in the circumstances would appear to be the obvious one. Relevant information regarding income, etc., and local dietary costs having been obtained in regard to an individual presumed to be in need of help towards obtaining an adequate diet, the data are available for deciding whether the individual in question should receive it on the grounds of actual lack of money. If so, it would appear that appropriate action should be taken on the spot not only on humanitarian grounds but also—if the position is accepted that private personal affairs are a public concern to the extent of justifying an inquiry—in order that the work done in carrying out this invidious task (which incidentally a promise of "relief" would render less arduous) should not be wasted. Such cases, indeed, constitute merely a special subsection of unemployment benefit and public assistance—special in the sense that particular care has to be taken that assistance is necessary because of actual lack of money and that, when afforded, it arrives at its true destination.

The details of how such a scheme could be made to function in practice have already been indicated in outline in a previous letter (*Journal*, June 30, p. 257). It is obvious also that in carrying it out data much more reliable than could otherwise be obtained might be collected, which data would have reference not only to alimentation in regard to the state of nutrition but also to other even more important factors having a bearing on it, if such an undertaking did not prove to be too intricately complicated and impracticable.—I am, etc.,

Aberdeen, Oct. 31.

J. P. MCGOWAN.

Safe Childbirth

SIR,—In my book, *Safe Childbirth: The Three Essentials*, I have pointed out that easy labour depends not only on a well-shaped pelvis but also on flexible pelvic joints, and that such flexibility can be attained by correct exercises practised during pregnancy so that the pelvis may expand at the joints (sacro-iliac and pubic symphysis) during the act of birth. For this to occur those postures should be advocated which are adopted instinctively by most women if left to do as they like at the time of confinement—squatting, crouching, kneeling. So far in England I have not found a maternity hospital where I can have patients trained in the correct exercises and postures and confined in the posture best suited to them. To confine crouching a woman whose joints are rigid and whose pelvic floor is contracted is to court disaster—though I find that patients whose joints are flexible (whether naturally or after appropriate exercises) have easier and quicker confinements even if not allowed to assume the postures I advocate for delivery.

My conviction is that neither doctor nor midwife is to blame for our maternal mortality rates, but the mother herself, who must be taught she is an active agent, not a passive sufferer. She must regard herself as an athlete in need of training for her special job, not a poor invalid who must lie down and have the sympathy and prayers of all lest she die of it. Sister Randell of St. Thomas's, with her thirty years' experience, has developed in accordance with this idea a series of suitable ante-natal exercises to increase this natural mobility of the pelvic joints, with other exercises, of an opposite character, to be done during the puerperium to strengthen those muscles which draw

the component parts of the pelvis together. It was necessary to find out what postures seemed most agreeable and natural to the patients during labour. To this end Miss Randell provided the patients with paper and pencil to record their impressions. We have secured some valuable information from this source alone, outstanding being the fact that the posture on back or side was most painful and never willingly assumed. Patients prepared on these lines have easy confinements and regain their normal figure almost at once, as photographs show.—I am, etc.,

London, W.1, Nov. 5.

KATHLEEN VAUGHAN.

Undulant Fever

SIR,—A report of another case of *Brucella abortus* infection may be of interest.

On November 11, 1937, I was called to see a male, aged 32, who gave me a history of having felt sleepy in the afternoons and evenings for a period of about ten days, and, in fact, of having dropped off to sleep while reading the paper on returning from his office. He complained of violent headache and vomiting; his temperature was 102.2° F., his pulse and respiratory rates were correspondingly raised, and his tongue was slightly furred. Clinically I could find no cause for his condition, and made a provisional diagnosis of gastro-intestinal influenza. I treated him symptomatically, prescribing a fluid diet with phenacetin, caffeine, and bismuth carbonate. On the following day his headache and vomiting had ceased and his temperature had dropped to 100° F. After five days his temperature was between 98.4° and 99° F. in the mornings and between 99° and 100° F. in the evenings. The patient said he felt quite well and wanted to get up; this, of course, I refused to allow. At the end of twelve days, on November 23, I observed a few spots—perhaps eight—vaguely resembling rose spots, on the thorax and abdomen. The temperature was still between 99° and 100° F. from 6 p.m. to 10 p.m., but was normal at all other times; the tongue was still slightly furred. I thought of the possibility of one of the enteric group of fevers or undulant fever, and took some blood; the following is a copy of the pathologist's report:

"Negative for *B. typhosus* in dilutions of 1:10, 1:25, 1:50, 1:100, and 1:250. Negative results also obtained for *B. paratyphosus* strains A and B in similar dilutions. With *Brucella abortus* agglutination takes place in dilutions of 1:50, 1:100, 1:500, and 1:1,000, but dilutions of 1:2,500 and 1:5,000 remain negative."

I then tried protein shock therapy with T.A.B. vaccine. The intravenous injection was given at 10 a.m., and by 10 p.m. on the same day the temperature had risen to 105° F. and the pulse rate to 104. The patient was feeling sick, had a violent headache, and was sweating profusely. Next morning his temperature was 97.2° F.; it remained subnormal for two days, then became normal.

The patient made an uninterrupted recovery. He has not suffered any recurrence or relapse although nearly a year has elapsed.—I am, etc.,

J. A. KENNETH DOUGLAS.

Neyland, Pembrokeshire, Nov. 2.

The international committee for instruction and action as regards the protection of the civilian community in time of war, which was set up at Luxembourg on July 4, met on October 28 at the Grand-Ducal Palace, and considered first its three-monthly review, *The Protection of the Civil Population in War*, the first number of which has already been published in Paris. Subcommittees have been constituted to deal with propaganda, diplomacy, military matters, medical treatment, legal questions, civilian defence, and protection of women; the activities of these subcommittees are beginning at once. The next meeting of the international committee will be held in Luxembourg next January.

Medical Notes in Parliament

Civilian Defence

Speaking on November 1 on the appointment of Sir John Anderson the Prime Minister said he would in fact be the Minister for Civilian Defence. He would have charge of air raid precautions and also be responsible for determining arrangements for national voluntary service. Mr. Chamberlain added that the Ministry of Health was in close touch with local authorities, and was responsible for the medical services, including nursing and ambulance provision. Other Departments concerned included the Board of Education, which must marshal children in case of evacuation. It was necessary that the activities of all the different Departments should be co-ordinated, so that each might know beforehand exactly what would be expected of them in an emergency.

On November 1 Mr. Lloyd informed Mr. Simmonds that action had already been taken, on the report of the Anderson Committee on Evacuation, both in the light of the recommendations in the report and of the experience gained during the recent emergency, to examine and prepare in detail evacuation schemes. Steps had been taken before the recent emergency to have ready schemes such as could be operated at once if there were no time for lengthy preparation. Information was given in the Press about such a scheme which had been prepared for London. It was, however, fully recognized that with time for preparation much could be done to improve such schemes, and the detailed work necessary for this purpose was in progress.

The King's Speech

The speech from the Throne outlining the programme of business for Parliament in the new Session was read by His Majesty the King in the House of Lords on November 8. In the course of it the following declarations were made:

The problems of civil defence, including that of the effective utilization of the resources of the nation for national voluntary service, will in future receive the undivided attention of a Minister—the Lord Privy Seal.

My Government will press forward with better housing, both urban and rural, and will proceed with the development of the educational services. They will vigorously continue the campaign for the improvement of the public health, and in particular will submit to you proposals for the earlier and more effective treatment of cancer.

The policy of My Government will continue to be directed to improving conditions in the special areas.

A Bill will be laid before you to amend the penal law dealing, in particular, with young offenders and those who commit repeated offences.

Measures will be laid before you to assist the production, improve the quality, and increase the consumption of milk.

Among the measures which you will be invited to pass will be Bills to amend the law relating to the carrying on of the business of insurance; to amend the Unemployment Insurance Acts; and to raise the amount of the Miners' Welfare Levy, in order to provide additional funds for the building of pithead baths.

A Bill will be submitted to you for the purpose of re-organizing Scottish administration, and centralizing the Government Departments in Edinburgh. Further action will be taken to deal with slums and overcrowding in Scotland, and a measure relating to the financial provision for this purpose will be submitted to you. You will also be invited to consider other Scottish measures, including a Bill for the amendment of the marriage law.

Debate on the King's Speech

During the debate in the House of Lords on November 8 on the motion for an address in reply to the King's Speech Lord STANHOPE gave an assurance that there was no intention on the part of the Government to curtail the social services of the country. He pointed out that in the King's Speech there was a reference to an effort which would be made to deal with cancer, a disease which had replaced tuberculosis as the greatest scourge afflicting mankind. Its seriousness could be gauged from the fact that, according to his information, cancer was responsible for no fewer than 200 deaths a day.

The debate on the address was adjourned until November 10.

IN THE HOUSE OF COMMONS

In the House of Commons, on November 8, the motion for an address of thanks in reply to the King's Speech was moved by Mr. Hely-Hutchinson and seconded by Mr. Markham. Mr. MARKHAM said he was glad to notice the reference to the Government's determination to eradicate cancer. This addition to the social services would be cordially welcomed in all parts of the House. The more effective treatment of cancer could not be carried out by the existing voluntary hospital system, and they would all like to see the most up-to-date methods, in co-operation with the local authorities, to set up adequate staffs and centres for the treatment of this great scourge. More than that, however, the great thing was to eliminate the ignorance, inertia, and fear which were the greatest allies of cancer in this country.

Mr. ATILEE complained that there was nothing in the King's Speech with regard to the social services, that there was no mention of unemployment, and that the Government was equally vague on the question of the special areas. Nothing was said about the condition of the people nor about old age pensions. The Labour Party considered that the foundation of the national strength was in the condition of the people, and that a sound policy of nutrition was a basis of strength; and that that could not be obtained through a means test. The Labour Party welcomed the proposals for the reform of the penal system, the proposals to deal with cancer, and those relating to pithead baths.

GOVERNMENT REPLY

Mr. CHAMBERLAIN said that the Minister of Civilian Defence (the Lord Privy Seal) would give his prompt and undivided attention among other subjects to the evacuation of the civil populations from certain places in times of emergency. The second point which would occupy the Minister's attention would be the provision of adequate shelter accommodation in vulnerable areas. On the subject of national voluntary service a good deal of preliminary planning had been done for the mobilization of the nation's man power, and the Minister would accordingly find a considerable amount of material ready to his hand when he came to formulate his plans under that head.

NO REDUCTION IN SOCIAL SERVICES

With regard to the social services, it was not to be expected that we could at once and at the same time embark on an enormous armament programme, the whole cost of which we were not yet in a position to estimate, and face projects of social improvements which would lay on the taxpayers fresh and impossible burdens. There was no foundation for any suggestion that the Government was contemplating cuts in the existing social services. Nothing that had been said by any Minister gave any foundation for such an accusation, and, as the King's Speech showed, the Government was still making further extensions of the social services. The provisions for public health, the work of housing, and the clearing of slums and providing for overcrowding still went on vigorously. A new proposal mentioned in the King's Speech for making a frontal attack on that perhaps most frightening of all diseases, cancer, would,

he knew, have the approval of all parts of the House. Mr. Attlee had mentioned nutrition, and had spoken as though, because the word did not appear in the King's Speech, it must necessarily be absent from the minds of the Government. It had been in his own mind for many years since a conversation which he had, when he was Minister of Health, with the late Sir Walter Fletcher, who had said to him that by a comparatively small expenditure on teaching people how to feed themselves and their families we could do more to improve the health and physique of the nation even than by the greater efforts which were then being made at the Ministry of Health to improve housing conditions. That statement was so striking that it made a very deep impression on his mind, and as a matter of fact the Minister of Health to-day was engaged on the most far-reaching and comprehensive inquiry into the food habits of the people that had ever been made in this or any other country. Everybody would agree that the more information they had about this subject the better, in order that when they did proceed they might be building on solid ground and be certain they were proceeding on right lines. Referring to agriculture, Mr. Chamberlain said that the most important measure and one of the earliest to be introduced would be the new Milk Bill. The main principle of the Bill was to encourage the consumption of liquid milk, alike in the interests of the farmer and of national health.

The debate was adjourned.

Civil Population in Air Attack

On November 3 Mr. HERRERT MORRISON opened a debate on protection of the civil population in air attack. He said that during the crisis there was a deficiency in the number of gas masks in some localities and some masks were delivered short of vital parts; there were mental hospitals under the care of the London County Council which had not received gas masks to this day. On the subject of hospitals Mr. Morrison said the authorities had to anticipate casualties on a large scale. It was essential that the hospitals organized locally and centrally should trace the movements of the patient from the time he might be damaged in the street, to the first-aid centre, then through the casualty hospital to the base hospital. Ambulances and stretchers were needed. This business was nowhere more vital than in London with its numerous local authorities and hospital authorities. Since 1930 there had been five different inquiries on this subject. Four of these ended without reaching conclusions; finally came a report of the Wilson Committee presented on July 20, 1938. The crisis came in September, and there was no time to finish the plan for the organization of the hospitals. Supreme direction was then undertaken by the Ministry of Health. Fortunately, the London County Council was reasonably prepared and ready with medical reserves and food reserves. In structural precautions in hospitals the council, like other authorities, was not so well prepared, because technical advice was not supplied by the Home Office until June 17, 1938. The story was the same with ambulances. No additional stretchers had been received when the crisis was acute. To supply them was a Government responsibility, and when, under pressure from the London County Council, the Ministry of Health assumed general ambulance responsibility a supply of 4,000 was secured by the end of the crisis week. After the Ministry of Health had taken that responsibility from the Home Office, it issued a circular on September 23 instructing the Metropolitan Borough Councils to earmark ambulances, although it should have known that ambulance organization was the duty of the London County Council under the Air Raid Precautions Act and under the regulations made by the Secretary of State. The boroughs were responsible for first-aid stations, which ought to have been under the Ministry of Health. These were short of medical supplies and of stretchers.

Sir SAMUEL HOARE replied for the Home Office, and pointed out that local authorities had been slow in acting upon Home Office circulars about the reception and distribution of respirators. Eventually the Home Office had to act on its

own initiative, and within a few days over 38,000,000 were distributed.

Mr. R. C. MORRISON said the Ministry of Health was not helpful during the crisis. The local hospitals had no advice or information at all. The voluntary hospital in his constituency (Tottenham, North) was unable to inform the local authority whether it was to be regarded as a base hospital for air raid precautions. The Home Office in the middle of the crisis instructed local authorities that they should distribute to every house in the United Kingdom a booklet principally occupied with information on how to make rooms gas-proof. On the day that booklet was distributed a conference was held at the Ministry of Health, and representatives of voluntary hospitals were there told that "as regards gas-proofing, gas is no longer considered to be a major risk, and it is not thought that any special precautions should be taken."

Sir JOHN ANDERSON, speaking for the first time as Minister responsible for Air Raid Defence, said the question of how to fit in the local authorities would have to be looked at afresh in the light of recent experience.

LONDON VOLUNTARY HOSPITALS DURING THE CRISIS

Colonel NATHAN said he had asked question after question in the House on what was expected of voluntary hospitals, but no information was forthcoming. He was concerned with two voluntary hospitals. One was a special hospital and the other was a great teaching hospital. Both were within the danger area. The special hospital was the Infants Hospital in Vincent Square, and the teaching hospital was Westminster Hospital, where he was chairman of the committee charged with air raid precautions. For months efforts were made to discover what the hospitals were expected to do with their patients, their staffs, and their buildings; what would be their functions in the case of air raids; and where the expense would fall. To none of these inquiries was any answer forthcoming. Only on the day when the Prime Minister's journey to Berchtesgaden was announced were the first steps taken. A meeting of representatives of the teaching hospitals was suddenly summoned at the Ministry of Health, and the Director-General stated that the hospitals emergency service had just been created. Colonel Nathan interposed the remark that Colonel Hebb, Director-General of this emergency system, assisted in the London area by Dr. Dobbie on the London County Council, from that moment gave unstinted service and was of the utmost help. He said the statement made at the meeting in the Ministry was: "Gentlemen, this emergency hospital service has just been created. You must expect bombs to fall on London at any moment. Do the best you can."

No written instruction was ever issued from beginning to end. They were told they must evacuate their hospitals. When they asked how, they were told that ambulances would be provided but that arrangements had only that day been made for conversion of rolling stock and road transports to take stretcher cases and that the services would not be available for three weeks. They were told to increase the amount of hospital accommodation by 30 or 50 per cent., but not a blanket, mattress, or a bedstead had been ordered. When the Ministry of Health was asked what they were going to do they said they were going to commandeer blankets and bedsteads from Harrods, Selfridges, and elsewhere. It was unforgivable that no steps of any kind had been taken, because every casualty resulting from air raids would have to be treated in some hospital. They were told to provide emergency stores, but at the same time that they were asked as voluntary organizations to do all these things they were told that if there was no war the Government would not pay anything for them. They were to make these arrangements at the expense of charitable funds, and if there was a war some unspecified contribution would be made from Government sources.

The two hospitals for which he spoke were, within a week of the first instructions, to inform the Ministry of Health that they were ready to take emergency cases to an extent greater by 50 per cent. than their ordinary accommodation. They acted upon their own initiative and sought no Treasury consent. They had many difficulties. The Home Office was

unable to provide a sufficiency of gas masks, not only masks for patients but duty masks for the staffs. His interpretation of the Government instructions on gas protection in hospitals was that in a hospital, with the constant traffic of patients in and out, it was impracticable to have complete gas protection. They were advised that special accommodation and gas-proof rooms should be made for cardiac and other chest cases and for the protection of food. They were told that there would be officers from the local mortuary who would deal with the dead. When they asked the local authorities what arrangements they had made for the dead, the reply was that the authorities had no instructions and no information, and no intention, unless instructed, of dealing with the situation. That was an instance of the lack of co-ordination between Government Departments and between the central and local governments.

As regards the special hospital in Vincent Square, originally it was to be a Grade "A" hospital for infants; later, after they were fully equipped to deal with children who might be injured, they were told that this Infants Hospital was to be transformed at once into an adult casualty clearing station. They set about the change, and in a week the hospital was ready to receive, instead of 100 infants, 175 adults. He informed the Ministry of Health that the hospital had operating instruments only for infants and no surgical instruments for adults. He asked where they could get the latter, and how the expense would be borne. The Ministry said it had no instruments and could not help the hospital to get them, and that if the hospital bought them they would not get any grant from the State if there was no war. Thus the hospital was asked to take the whole of the risk, and it took it.

Then there was the question whether men and women should be treated in the same hospital. This was not simple when dealing with casualties resulting from air raids, which would be either gas or surgical casualties. In the ordinary way men went to the men's wards and women to the women's wards, but in a casualty clearing station, with a constant flow of casualties coming in and going out to the base hospitals, that could not be done, and both would have to remain for a time in the out-patient department. The Home Office said that men and women would have to be separated, but he doubted whether this was practicable in the same hospital. Another point was how were casualties to be directed to the various hospitals. It was essential that first-aid stations and hospitals should be under the same general and central direction and administration. It had so far been arranged, on the whole, that no medical officer should be attached to first-aid stations, whereas it was imperative that there should be a medical man in charge of each. It would be impossible for the hospitals to cope with the inrush of casualties unless these had first been sorted into the more and the less serious cases by some responsible person. He hoped to have an opportunity of discussing with the Minister some of the difficulties with which hospitals were confronted.

Mr. Herbert Morrison's motion was defeated by 355 to 130 and an amendment was carried which, while taking note of existing deficiencies in the system of civilian defence, welcomed the decision of the Government to entrust the system to a Minister appointed for that purpose and to complete with the utmost speed the measures necessary to provide for the country's need. This amendment was carried without a division.

Answering, on November 3, questions about air raid precautions, Mr. GEOFFREY LLOYD said contracts for the manufacture of 45,000,000 civilian respirators had been made. Approximately 4,000,000 civilian respirators had been issued to the metropolitan boroughs and the city of London, and had been distributed to the public. The instructions issued by this country about methods of protection against gas remained unaltered.

Undulant Fever in Great Britain

Mr. W. S. LIDDALL asked on November 3 the number of human cases of undulant fever arising in Great Britain attributable to bovine infection through milk or meat in each

of the past ten years, and what measures were taken to reduce the risk of human infection by the group of *Brucella* organisms. Dr. ELLIOT, in reply, said undulant fever was not a generally notifiable disease and statistics of its incidence were not available. Estimates had been made by responsible investigators that there might be some 400 or 500 cases per annum in this country. The importance of all measures to ensure the cleanliness and safety of milk in order to avoid risk from this and other milk-borne diseases had frequently been emphasized by the Ministry of Health. Considerable progress in this matter had been made. He had no information to suggest that meat was a source of human infection with this disease.

On the same day Mr. LIDDALL asked what proportion of tested milch cows in Great Britain showed evidence of *Brucella* infection as manifested by agglutination blood tests. Mr. W. S. MORRISON replied that no statistics were available on the proportion of milch cows submitted to the agglutination test which reacted, but the general view was that about 40 per cent. of dairy cows were infected. Where at a routine clinical inspection of a dairy herd, or at a special inspection made following a report from a local authority that suspicion attached to certain milk, a milch cow was found by a veterinary inspector showing clinical signs of the disease, the sale of the milk of such animal was prohibited by Section 5 of the Milk and Dairies (Consolidation) Act, 1915. The problem of contagious abortion in cattle had been under investigation at a number of institutions under the aegis of a committee of the Agricultural Research Council appointed in consultation with the Medical Research Council.

Insurance Practitioners in England and Wales.—On January 1, 1937, 16,812 medical practitioners in England and Wales were under agreement with insurance committees. The total amount paid them from national health insurance funds in respect of the year 1937 was £8,050,108.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

A. M. Barrett, M.B., B.Ch., of Pembroke College has been appointed University Demonstrator in Pathology for three years from October 1, 1938.

At a Congregation held on November 4 the following medical degrees were conferred:

M.D.—L. Foulds, D. W. C. Gawne, G. Rocyn-Jones.
M.B., B.Chir.—*T. J. Fairbank, *G. H. Baines, *T. L. Barbour,
*R. I. C. Bradford, H. W. Adeney.
M.B.—*G. Williams.

The degree of M.A. was conferred on G. D. Channell and F. W. Smith, University Demonstrators in Anatomy.

* By proxy.

UNIVERSITY OF LONDON

Ian M. Macgregor has qualified to receive the Academic Post-graduate Diploma in Public Health.

The Senate on October 19 awarded the degree of Ph.D. in Hygiene and Public Health (non-clinical) to S. Mukhopadhyay.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN

The following scholarships have been awarded for 1938-9:
Sir Owen Roberts Memorial Scholarship: Miss M. V. Teichmann. *A. M. Bird Postgraduate Scholarship in Pathology*: Miss N. T. F. Crowley. *Mabel Webb and A. M. Bird Research Scholarship*: Miss M. V. Sudds.

Lectures

A course of three lectures on "The Pathogenic Trypanosomes of Africa and the Tsetse Flies (*Glossina*) that Convey Them" will be given at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., by Dr. H. Lyndhurst Duke on Tuesday, Wednesday, and Thursday, November 15, 16, and 17, at 5.30 p.m. At the first lecture

the chair will be taken by Dr. C. M. Wenyon, F.R.S., director-in-chief of the Wellcome Bureau of Scientific Research. The lectures, which will be illustrated, are addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

Studentship

Applications are invited for the Geoffrey E. Duveen Traveling Studentship, of the value of £450, for research in any aspect of oto-rhino-laryngology. The studentship is normally tenable in the first instance for one year, part of which shall be spent in study abroad, in accordance with a scheme to be approved by the Studentship Board, but it may be extended for six months or for one or two years, and during the extended period the student may be allowed to undertake research at the Royal Ear Hospital or some other laboratory approved for the purpose. Full particulars can be obtained from the Academic Registrar, University of London, W.C.1, and prescribed forms of application must reach him not later than December 31.

UNIVERSITY OF LIVERPOOL

At a meeting of the University Council, held on November 1, C. V. Harrison, M.D., first assistant in morbid anatomy at the British Postgraduate Medical School, was appointed Senior Lecturer in Pathology from January 1, 1939, in place of Dr. T. F. Hewer, who has been appointed to the Chair of Pathology in the University of Bristol.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At the quarterly comitia of the Royal College of Physicians of London, held on October 27, with the President, Dr. Robert Hutchison, in the chair, Dr. C. M. Hinds Howell, Dr. A. C. D. Firth, Dr. F. E. Tylecote, and Dr. Bernard Hart were elected councillors.

The following Fellows were elected representatives of the College: Dr. H. L. Tidy on the committee of management of the Conjoint Board; Sir Comyns Berkeley on the council of the Central Midwives Board; Dr. John Hay on the court of governors of the University of Liverpool; Sir Stanley Woodward on the Central Council for District Nursing; Sir Arthur MacNalty on the executive committee of the Imperial Cancer Research Fund; and Dr. R. D. Gillespie at the conference of the National Council for Mental Hygiene, January, 1939.

The President announced that Dr. R. E. Smith had been appointed Milroy Lecturer for 1940, his subject to be "Acute Infectious Diseases at School"; that the Jenks Memorial Scholarship had been awarded to John Vesey Aveling, late of Epom College; and that the first awards of the Linares Scholarships, recently instituted by the College, had been made to G. M. Scott and T. Stapleton, late of King's School, Canterbury.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

Margaret Ball, M.D.Camb., R. Bolton, M.B., W. G. Brander, M.B.Camb., D. G. Freshwater, M.B.Camb., D. M. T. Gardner, B.M.Oxf., M. Gelfand, M.B. Capetown, F. T. Grey, M.B.Sydney, J. D. Hardy, M.D.Belf., B. G. Haynes, M.B.Sydney, H. B. Hunt, M.D.Birm., N. F. Lilawala, M.B.Bomb., J. D. Robertson, M.D. St. And., M. Sarwar, M.B.Punjab, S. R. F. Whitaker, M.B.Camb.

Licences

Licences to practise were conferred upon the following 139 candidates (including twenty-three women) who have passed the final examination in medicine, surgery, and midwifery of the Conjoint Board, and have complied with the necessary by-laws:

D. C. Arnott, Gladys M. Auchinleck, H. B. Austin, J. C. Ballantyne, A. M. Bennett, W. M. Bennett, E. S. Binns, M. W. Bird, A. N. Blades, F. A. Boggiano, T. W. Branch, Mary Brandon-Jones, R. T. Brooks, D. C. Brown, P. A. K. Brownlee, J. F. Buckmaster, J. A. Burnett, K. C. Burrow, A. Caplin, Phoebe Charlton, P. S. Cheshire, M. M. R. Clarke, A. Conachy, W. H. R. Cook, Patricia G. Cooper, C. C. Coplans, A. W. J. Craft, C. McK. Craig, E. J. Davis, W. W. Deane, Ursula M. Dick, B. Donnelly, M. N. S. Duncan, A. R. P. Ellis, C. J. Evans, G. M. Evans, R. W. Evans, Margery Feachem, T. Fenwick, E. L. V. Fitch, D. S. Foster, J. B. Franklin, Beryl M. Gee, R. C. R. Gethen, Janet D. Gimston, T. Griffiths, Hilda B. Grinyer, H. Haggag, N. J. Haggan, N. H. Halper, P. J. Hardie, R. F. E. Harrington, J. W. S. Harvey, R. J. Healey, R. D. Hearn, F. D. Hindmarsh, E. R. Hodgson Todd, R. O. Holland, J. G. S. Holman, Doris I. E. Huband, E. G. Hudson, J. P. W. Hughes, R. D. S. Jack, H. Diplomas

Diplomas were granted, jointly with the Royal College of Surgeons of England, to the following candidates:

DIPLOMA IN PUBLIC HEALTH.—B. Adak, Joan Butterworth, M. A. K. Durani, A. B. R. Finn, Lorna M. A. Goulden-Bach, R. D. Gray, A. B. Guild, F. C. Hilton-Sergeant, C. W. C. Karran, H. D. Palmer, H. R. Rishworth, H. L. Seile, H. K. Shahani.

Diplomas in Child Health were granted to the thirty-four candidates whose names were included in the report of the meeting of the Council of the Royal College of Surgeons of England in the *Journal* of October 22 (p. 870).

Dr. Morley Fletcher left England on October 28 for Australia, where he will act as representative of the Royal College of Physicians of London at the opening of the Royal Australasian College of Physicians. The Royal College of Physicians of London is presenting an illuminated address and a replica of its silver wand or caduceus, which was presented to the College by Caius in 1556.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The annual meeting of Fellows and Members will be held at the College in Lincoln's Inn Fields on Thursday, November 17, at 4 p.m., when a report from the Council will be laid before the meeting. Fellows and Members can obtain copies of the report on application to the secretary, and can have their names placed on the list of those to whom it is sent annually. A copy of the agenda will be issued to any Fellow or Member who may apply for one.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At the quarterly meeting of the Council, held on October 29, with the President, Sir Even Maclean, in the chair, Denis Valentine Morris (Galway) and William Keverall McIntyre (Tasmania) were elected to the Membership of the College.

Thomas Charles Clare (Leicester) was admitted to the Fellowship.

The following were admitted to the Membership:

Arthur Charles Belfield (New Zealand), *Phillip Godfrey Chalewood (India), Johannes Cornelius Coetzee (South Africa), *Gladys Story Cunningham (China), James Bruce Dewar (Edinburgh), *John Edis-Myers (India), Llewelyn Mervin Edwards (London), Arthur Bryant Evans (London), Agnes Jean Herring (Dundee), Donald Forsyth Lawson (Australia), Thomas Emmet Lennon (Liverpool), Charles Rutherford Morison (Harrogate), Henry Anthony Rippiner (Bradford), Dorothy Anderton Sharpe (London), Pittapalayam Veraswami Venkatswami (India), *Harry Silvester Watts (India).

* In absentia.

At the termination of the meeting Mr. G. F. Gibberd assumed the office of honorary secretary and Professor William Fletcher Shaw assumed the office of President. A vote of great appreciation for the services of Sir Even Maclean during the past three years as President and during the whole period since the inception of the College was adopted by the Council.

The following candidates for the diploma of the College have satisfied the examiners:

O. G. Bark, Dorothy M. Brook, Isobell Brown, H. Burton, S. J. Cohen, R. R. Foote, G. R. Griffiths, L. Langmore, J. B. F. McKenzie, Agnes M. Mitchell, G. D. Owen, Constance E. Peaker, R. G. Record, E. R. Rees, H. G. Roberts, Una R. Roy, S. A. Scorer, Marjorie Swain, W. G. Swann, J. F. Swan, J. D. Watt, R. H. Vasey, H. S. Wigfield.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At the annual meeting of the Royal Faculty of Physicians and Surgeons of Glasgow the following officers were elected: *President*, Dr. John Henderson; *Visitor*, Dr. J. Souttar

McKendrick; *Honorary Treasurer*, Dr. James H. MacDonald; *Honorary Librarian*, Dr. W. R. Snodgrass; *Representative for the General Medical Council*, Mr. G. H. Edington.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the examination indicated:

DIPLOMA OF L.R.C.P.ED., L.R.C.S.ED., L.R.F.P. AND S.GLAS.—
C. G. Adams, A. C. B. Allan, M. Y. Anthony, S. A. Antonious, R. E. G. Armattoe, S. N. Banerji, G. A. Bell, J. A. Brown, R. A. Brown, P. Chatterjee, B. Crawshaw, S. Edelson, Frieda Ehrlich, W. V. A. Erskine, A. F. A. Fairweather, N. L. Freund, H. S. Friedlander, B. M. Heller, Kate Hermann, B. Hirschson, F. J. Hoenigsberger, R. B. Hollos, J. K. Houston, T. Shih-Do-Hsu, S. Kambourian, F. Kreuter, W. Lubansky, J. C. McGrath, J. L. Markson, S. T. B. A. Mattar, K. Meyerhof, E. Mintz, S. Mirk, A. G. Mohammed, W. Morron, R. D. Oliver, S. Oshinsky, G. Pickar, B. Pribram, I. B. Radow, D. Raeside, P. Rosenbaum, J. Schlosser, J. M. Silverstein, D. Simenoff, R. Sorkin, Marie H. Stevenson, E. S. Sutherland, A. Shapiro, A. Taterka, J. Tolland, A. Waheed, B. J. S. Wessels.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

For the first time in four weeks there has been a decline in the incidence of poliomyelitis in England and Wales—70, compared with 81 in the previous week; in London there were 4 cases as against 11. In Scotland and Ireland the disease also appears to be on the decrease. The counties chiefly affected in England and Wales were: Leicester 8 (Leicester 1, Melton Mowbray 2, Shipshed 3, Melton and Belvoir 2); Gloucester 6 (Bristol 4, Cirencester 1, Nailsworth 1); Lincoln 6 (Scunthorpe 4, Stamford 1, South Kesteven 1); Essex 5 (Tendring 2, and 1 each in Braintree and Bocking, Harwich, Romford); Glamorgan 5 (Cardiff 4, Neath 1); Southampton 5 (Droxford 2, and 1 each in Winchester City, Winchester Rural, Havant and Waterloo); Kent 4 (Bronley 1, Tunbridge Wells 2, Herne Bay 1); London 4 (1 each in Deptford, Fulham, Hackney, and Lewisham); Oxford 3, all in the City of Oxford. The three cases in Scotland occurred in Aberdeen, Edinburgh, and Paisley.

In Germany during the week ended October 15 the number of cases of poliomyelitis rose from 353 to 364; the chief areas affected were: District of Cologne 42 (27), Düsseldorf 16 (13), Swabia 23 (16), Saxony 39 (27), Baden 26 (16), the Saar 12 (7). In Holland during the week ended October 22 the number recorded, 33, was the same as in the preceding week; of these 13 (10) were in the province of South Holland.

Enteric Fever

Notifications of enteric fever in England and Wales fell from 37 to 19, and in London from 12 to 1. In Scotland, on the other hand, a rise from 4 to 7 was recorded, while in Ireland the figures were identical in both weeks. More than one case was notified in the following counties: Berks 3 (Windsor 2, New Windsor 1); Sussex 3 (Chichester 2, Hastings 1); Salop 2 (1 each in Oswestry and Shrewsbury); Middlesex 2 (1 each in Hendon and Southgate). The London case occurred in the Borough of Hackney. Of the 7 cases reported in Scotland 3 were notified as paratyphoid fever in Lanark County, while 1 case of typhoid fever was notified in Airdrie, Glasgow, and Lanark County. One case of typhoid fever was notified in the County of Midlothian.

Primary and Influenzal Pneumonia

An appreciable increase is noted in the notifications of primary and influenzal pneumonia in England and Wales (578, compared with 534 in the previous week), in which London shared (65, compared with 45). The counties mainly affected were Lancaster 94, of which 32 were in Manchester

and 16 in Liverpool; Yorks (West Riding) 70, 24 in Sheffield and 8 in Bradford; Warwick 45, of which 32 were in Birmingham; Durham 41; Stafford 30. Deaths from influenza in the 126 Great Towns fell from 26 to 22; more than one death was reported in London and in Birmingham, the numbers being 4 and 3 respectively.

Encephalitis Lethargica

The reports furnished to the Health Section of the Secretariat of the League of Nations indicate that there were no major epidemics of encephalitis lethargica in any country in the years 1936-8. During 1936 considerable increases over the mean for the preceding five-year period were observed in Germany and Japan. In the latter country 1,005 deaths from encephalitis lethargica were recorded in 1936. In the United States of America cases rose from 723 in 1936 to 1,068 in 1937; the chief areas affected were: New York State 121; Illinois 104; Missouri 190; Texas 47; California 75.

Diphtheria and Scarlet Fever

Diphtheria continues to spread in England and Wales—1,432 for the week under review, compared with 1,367 in the preceding week—while a fall was noted in London, from 173 to 153. In Scotland and Eire considerable increases were recorded during the week. The chief centres affected were: Liverpool 59 (57), Manchester 28 (32), Bristol 23 (20), South Shields 21 (19), Leicester 15 (23), Newport 15 (8), Lewisham 14 (13), Poplar 13 (6). Of the 27 deaths from diphtheria in the 126 Great Towns 5 were in London and 2 each in Southport, South Shields, Stanley (Durham), and Birmingham. In Scotland increases were noted in Glasgow 101 (78), Dundee 21 (9), Lanark County 19 (11), and decreases in Aberdeen 14 (18) and Edinburgh 13 (14). There were three deaths, all in Glasgow.

In England and Wales notifications of scarlet fever rose from 1,864 to 2,000, and in London from 159 to 192. The chief centres affected were: Manchester 56 (47), Liverpool 50 (50), Wandsworth 26 (11), Camberwell 24 (10), Stoke-on-Trent 31 (30), Bristol 44 (30), South Shields 23 (15), Leicester 22 (14), West Ham 18 (18). There were two deaths, in London and Leeds.

Measles and Whooping-cough

One death from measles (in Birmingham) was recorded in the Great Towns. Of the 22 cases of measles notified in London 4 were in Deptford and 3 each in Stepney and Poplar. In Scotland 8 cases were notified, compared with 18 in the preceding week—Glasgow 6 (9), Edinburgh 2 (1). No deaths were reported from any of the sixteen Great Towns.

Of the five deaths from whooping-cough in the 126 Great Towns of England and Wales 1 each occurred in Dagenham, Tottenham, West Ham, Bradford, and Leicester. In London 146 (131) cases of whooping-cough were notified, chiefly in: Kensington 18 (8), Hackney 17 (21), Stepney 14 (9), and Wandsworth 13 (14). In Scotland cases rose from 163 to 178, notably in Glasgow 147 (134), Paisley 10 (6), and Edinburgh 8 (4). There was one death each in Motherwell, Wishaw, and Glasgow.

Cholera and Plague

During the week under review there were 578 (862) cases of cholera and 282 (433) deaths in the Central Provinces of India, 270 (330) cases and 128 (141) deaths in Bombay Presidency, 218 (223) cases and 97 (104) deaths in the United Provinces. In China 24 (87) cases and 6 (30) deaths were reported in Shanghai and 7 (7) cases and 5 (9) deaths in Hong Kong.

In India during the same week there were 43 (73) cases of plague and 6 (5) deaths in the Central Provinces, 67 (88) cases and 65 (73) deaths in Burma, 11 (25) cases and 8 (11) deaths in Madras Presidency, and 47 (13) cases and 23 (6) deaths in Bombay Presidency.

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended October 29, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for : (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for : (a) The 126 great towns (124 in 1937) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Obituary

JOHN MUNRO DUPONT, M.D.

The passing of Dr. John Munro Dupont, who died at his home on October 30, will be greatly regretted in Frome and the surrounding district. He was a son of the late Mr. and Mrs. Dupont of Ampthill, Bedfordshire, and was born in London in 1871. On his father's side he was of French Huguenot extraction: his mother was Scottish. From Bedford College he went to Edinburgh, qualifying in 1901 and taking his M.D. of that University in 1905. Shortly after qualifying he proceeded to South Africa with the R.A.M.C. to take part in the Boer War, and stayed there for nearly two years in the R.A.M.C. after the war was over. He gained the South African medal with four bars. Before starting in general practice he held the appointments of clinical assistant to the Samaritan Hospital for Women, London, resident medical officer to the Royal National Chest Hospital, and resident physician to the City Hospital, Edinburgh. For over thirty years Dr. Dupont practised in Frome, Somerset, where he held the post of honorary medical officer to the Victoria Hospital, an institution in which he took the greatest interest. He was, indeed, the main instigator of the scheme for the extension of the hospital which has since been carried out and was the first chairman of the Extension Committee.

Dr. Dupont joined the British Medical Association in 1904 and was chairman of the Bath Division in 1925, the year in which the Annual Meeting of the Association was held at Bath. He was the first country member to be elected to the Clinical Society of Bath (in 1920). At the outbreak of the great war he was captain in the Germanist's Mounted Brigade Field Ambulance, with cases of pe he served successively on the east coast, at areas affected in Egypt, whence he returned to England, on 16 (13), Swab of the death of his wife. Subsequently he acted Saar 12 (7). I officer in charge of ambulance trains in France, the number with the rank of major in 1919. In addition to week of the Holland. at the Victoria Hospital Dr. Dupont was medical for the Ministry of Pensions, medical officer to office, and medical officer to the Frome Town

Notifications o was twice married, and leaves a widow, from 37 to 19, ad a daughter. He was a strong supporter on the other hand, tive Party and an enthusiastic follower of in Ireland ticket. county cr

The following well-known foreign medical men have recently died: Professor RENÉ DU BOIS-REYMOND, for many years director of the University Physiological Institute of Berlin, like his father, and a pioneer in the science of sport, aged 75; Professor PAUL KRIZG, head of the German Hospital in Peking, aged 70; Dr. ARNO LOEWE, a prominent Dresden orthopaedic surgeon; Professor JOHANNES LANGE, director of the university clinic for nervous diseases at Breslau, aged 47; Dr. GEORGE E. DE SCHWEINITZ, an eminent ophthalmologist of Philadelphia, author of a textbook on diseases of the eyes, which passed through numerous editions, and former president of the American Medical Association, aged 79; Hofrat FERDINAND HUEPPE, emeritus professor of hygiene in the German University at Prague, aged 86; Dr. ERNEST SCHÜLTZE, emeritus professor of psychiatry at Göttingen, aged 73; and Dr. HERMANN GOCHT, for many years professor of orthopaedics at Berlin, aged 69.

CO-ORDINATION OF MEDICAL SERVICES

Deputation to Sir Thomas Inskip

A deputation from the Central Emergency Committee of the British Medical Association, together with representatives of the Royal Colleges of Physicians and Surgeons, was received on November 8 by Sir Thomas Inskip, Minister for Co-ordination of Defence, who was accompanied by officials of the Government Departments concerned. The members of the deputation, introduced by Sir Kaye Le Fleming, Chairman of Council of the British Medical Association, were: Dr. H. Guy Dain (Chairman of the Representative Body), Mr. N. Bishop Harman (Treasurer), Sir Alfred Webb Johnson, Dr. Clark Kennedy, Professor R. M. F. Picken, Sir Charles Wilson, Dr. Letitia Fairfield, with Dr. G. C. Anderson and Dr. C. Hill, Secretary and Deputy Secretary of the Association.

The deputation urged the establishment of machinery for the co-ordination of all medical services for the civilian population under a single body, and the co-ordination of the civilian medical organization with that of the Service departments. It also proposed that this machinery of co-ordination should be closely associated with the Central Emergency Committee of the B.M.A. as being representative of all branches of the medical profession.

In reply, the Minister said that he greatly appreciated the assistance given by the British Medical Association, especially in compiling an exhaustive survey of the profession. He expressed himself in sympathy with the principles put forward, and undertook that they would be examined by the Departments concerned. He assured the deputation of his desire to co-operate fully with the profession and to avail himself of their services.

A fuller report of the proceedings will appear next week.

The Services

The Princess Royal inspected Princess Mary's Royal Air Force Hospital, Halton, on October 29. She opened this hospital eleven years ago, and there were then 204 beds; this number has now been increased to 535. It is one of the most modern of Service hospitals, and has a new x-ray department, an isolation department, several additional wards, and a chapel. Other hospitals for the Royal Air Force are being erected as part of the extension programme. The Royal Air Force Nursing Service was created in June, 1918, and five years later, with the approval of King George V, it was designated "Princess Mary's Royal Air Force Nursing Service." It now includes a matron-in-chief, matrons, senior sisters, sisters, and staff nurses. Foreign service is undertaken in Iraq, Aden, and Palestine. The Princess Royal has previously visited Cranwell Hospital and the R.A.F. hospital at Sarafand in Palestine.

R. F. Schuurmans (*Nederl. Tijdschr. Geneesk.*, 1938, 82, 4799) records two cases of stricture of the vagina. The first was in a nullipara aged 30, who sought advice for sterility and dyspareunia. She showed the condition of cirrhosis sub-hymenalis described by Halban, which consists of a circular stricture situated beneath the hymen. The second case was that of a woman aged 50, who had a vaginal discharge and certain psychical disturbances connected with the climacteric. Examination revealed the condition described by Labhar as kraurosis fornicis vaginae. According to Schuurmans the cause of both these conditions is the same—namely, deficient secretion of follicular hormone associated with chronic trauma.

Medical News

The twenty-third Guthrie Lecture will be given before the Physical Society by Professor A. V. Hill, Sc.D., F.R.S., to-day, Friday, November 11, at 5.15 p.m., in the Physics Department of the Imperial College, Imperial Institute Road, S.W. The subject of the lecture is "The Transformations of Energy and the Mechanical Work of Muscles."

The Church Union Association has arranged an exhibition under the title of "The Family—To-day and To-morrow" at Caxton Hall, Westminster, S.W., from November 14 to 17. On Wednesday, November 16, at 3 p.m., there will be an address by Mr. F. J. McCann on "The Falling Birth Rate," with Dr. Halliday Sutherland in the chair.

A reception will be held at the Incorporated Liverpool School of Tropical Medicine, Pembroke Place, on Wednesday, November 23, at 8.30 p.m., when the Mary Kingsley medal will be presented to Dr. M. A. Barber, Professor E. Brumpt, Emeritus Professor W. S. Patton, and Professor W. Schulemann. Lady Danson is an honorary recipient.

The Congress of Rheumatism organized by the French League against Rheumatism which was to have been held in Paris on October 8 has been postponed to December 3, when discussions will be held on the clinical forms of rheumatism, medical treatment, physical treatment, surgical and orthopaedic treatment. The subscription for French and foreign doctors is 120 francs, and for members of the League 80 francs. Further information may be had from the Secrétariat de la Ligue Française contre le Rhumatisme, 23, Rue du Cherche-Midi, Paris, 6e.

The twelfth annual Radiological Congress and Exhibition will be held on December 7, 8, and 9 at the Central Hall, Westminster, S.W. Additional accommodation has been reserved, and the exhibition will be considerably larger than in the past. The nineteenth Mackenzie-Davidson Memorial Lecture will be given by Dr. G. Shearer, and the twenty-first Silvanus Thompson Memorial Lecture by Dr. R. Ledoux-Lebard. The annual dinner will be held on Friday, December 9, at Claridge's Hotel.

The Sir Frederick Hobday Presentation Fund has now reached its first £1,000, contributed by about 850 subscribers. This response has encouraged the committee to carry on in order to obtain the amount necessary for the object which Sir Frederick Hobday has in view—namely, the endowment of a chair of comparative medicine. The subscription list is still open, and contributions may be sent to the honorary secretary, Mr. E. T. Cox, 3, St. John's Avenue, Putney, S.W.15.

Professor G. Roussy and Dr. C. Oberling have presented to the French Academy of Medicine a report entitled, "Can the Tarring of Roads be considered as one of the Causes of the Recrudescence of Cancer of the Lungs?" Their answer is in the negative in so far as observations hitherto published are concerned.

The Stirling Branch of the British Medical Association celebrates its jubilee this year. The minutes show that preliminary meetings were held in 1888 and that the Branch was formally constituted in 1889. The occasion will be particularly celebrated at the annual dinner of the Branch to be held at Stirling on November 30.

The President and Council of the Royal Society have awarded the Davy Medal to Professor George Barger, F.R.S., in recognition of his distinguished researches on alkaloids and other natural products; and the Darwin Medal to Professor F. O. Bower, F.R.S., in recognition of his work in the field in which Darwin himself laboured.

Dr. O. H. Mavor has been appointed a member of the committee to advise the Home Office and the Scottish Office on matters connected with the administration of the Cinematograph Act, 1909.

Of 25,361 books published in Germany in 1937, 990 (3 per cent.) were medical works of which the average cost was 9.20 marks as compared with the average cost of 3.99 marks for all books.

According to official statistics the total number of births in 1937 was 630,000 in France, 892,000 in Poland, 955,000 in Italy, 1,279,000 in Germany, and 2,190,000 in Japan.

Some cases of tularaemia have recently been notified in Finland as well as in Soviet Russia and Sweden.

Dr. Tiffeneau, professor of pharmacology and materia medica, has been elected dean of the Paris Faculty of Medicine.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL. *Antilog*, Westcent, London.

SECRETARY, *Medisecra* Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh), and of the Office of the Cumann Doctuirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin).

QUERIES AND ANSWERS

Protection of Eczematous Face

DR. D. BRAHAM writes: I wonder if any reader could inform me of a preparation that could be used to protect the face of a patient with chronic eczema from the effects of the sun in the spring and summer. The preparation would have to be almost invisible, and in the form of a cream. Perhaps workers with ultra-violet ray apparatus could assist with suggestions, which would be gratefully acknowledged.

Cattle Ringworm in Man

DR. STEWART (Banbury) writes: I should be grateful if any reader would suggest a cure for cattle ringworm occurring in the human subject. My practice is in an agricultural district, and I have tried various remedies for this condition without success.

Treatment of Pruritus Ani

DR. R. E. M. TAUNTON (Hanwell, W.) writes: I would like to add a further note with reference to the recent contributions on the treatment of pruritus ani. Several years ago I read in your columns the suggestion that ung. metallorum should be used. This I have prescribed until recently. Now I prescribe "tar dermatant," a solution of coal tar in an analgesic resinous base put up by Parke, Davis and Co., and have found it the most valuable of all remedies. Wash the anus at bedtime with cold water (without soap), and apply the paint with a brush that is supplied with the bottle. Though I do not pretend that this is a permanent cure it is at least a temporary one, and it acts like a charm. It gives instant and lasting relief. In severe cases the paint can be applied twice daily, but once every few nights will usually be enough.

Treatment of Superficial Glossitis

Mr. S. RUSSELL (Gold Coast) writes in reply to the query by "O. M. N." with regard to the treatment of superficial glossitis in the *Journal* of September 10 (p. 604): May I suggest the administration of marmite. In this country, where the condition is common, marmite acts as a specific.

Medical Apparatus in 1816

Dr. J. N. COLLINS (Peterborough) writes: At the establishment of the Peterborough Public Dispensary in 1816 the physician was authorized to obtain (1) an electrical machine, and (2) an apparatus for recovery from suspended animation. Can anyone suggest what these were? Induced currents were not known until 1831, so the electrical machine was probably a frictional machine, but how was it used and for what purpose? But the second item is a puzzle.

Income Tax

Life Assurance Relief: Educational Policy

"ABBEY" took out a small education policy for his son in 1930. The amount assured is payable in annual instalments after he attains 14, or can be converted by him into an endowment policy. The inspector of taxes states that no relief is due in respect of the policy.

** If the policy provides for educational benefits if the child lives, irrespective of the life of the parent, then no relief would be due.

LETTERS, NOTES, ETC.

Educational Function of Tonsils

Dr. F. C. EVE (Hull) writes: The thoughtful paper by Mr. P. W. Leathart on the biological function of the tonsils in the *Journal* of October 22 (p. 835) prompts me to add an interpretation which I have long believed in but have withheld for lack of proof—namely, that the function of the tonsils is educational. Everywhere the body is protected against the entrance of invading organisms by epithelium. But the crypts of the tonsils are narrow crevices—unprotected by epithelium—penetrating deeply into a spongework crowded with lymphocytes. Mr. Leathart tells us that these crypts always contain living micro-organisms. These facts suggest strongly that each crypt acts like a turnstile or grid to admit germs to the fortress one by one so that the defending lymphocytes can become acquainted without risk with the "taste" of hostile germs prevalent in the outer world, of which otherwise they would remain in ignorance. Thus they are educated to prepare antibodies against future invaders of the same "taste." Indeed, in diphtheria the education may be too drastic. Each dividing lymphocyte must then pass on its education to its two daughter cells—in the tonsils or wherever else they wander in the lymph stream or blood. For an educational function of this sort the situation of the tonsils and adenoids is highly strategic—just where organisms from the teeth, from the nostrils, and from the food impinge. Peyer's patches, in the same way, are educated against varying organisms prevalent in the small intestine; we know that Peyer's patches swell in typhoid. The crypt-like appendix—richly supplied with lymphoid follicles—learns in more leisurely fashion how to produce antibodies against different and anaerobic organisms—nowadays a dangerous task. This interpretation—so reasonably suggested by structure and site—is supported by the fact that tonsils, adenoids, and appendix may be removed without detriment, for already the education of their "immortal" lymphocytes has been accomplished. (True, the tonsil may be useful as a filter, though not when it has become septic and harmful.) If all three organs were removed at birth their loss might well be serious, and the experiment should be tried with regard to the subsequent immunity of a newborn animal. Again, the mysterious thymus gland, containing as it does a reserve army of millions of uneducated lymphocytes, gradually removes itself when lymphocytes have been sufficiently educated elsewhere. So, too, do the tonsils. I have not referred to polymorphonuclear leucocytes, partly because I could quote a natural experiment (chronic pyuria with bacilluria, with and without haematuria) which showed clearly that polymorphonuclear leucocytes do not phagocyte organisms unless they have previously been opsonized—that is, the poly-

morphonuclear leucocytes are not educated to recognize hostile germs: the germs have first to be labelled dangerous before they can be devoured. What do pathologists say to these suggestions?

Distribution of Cancer

Dr. W. DALGLISH (Witney, Oxon) writes: The findings of W. E. Snell and H. A. Bathurst in the *Supplement* to the *British Medical Journal* of September 3 (p. 178) and of G. B. Leyton and H. G. Leyton in the *Journal* of August 21, 1937 (p. 378) with regard to the regional distribution of cancer, though seemingly contradictory, cannot be regarded as incompatible in view of the fact that Leyton and Leyton can demonstrate in microphotographs the presence in cancer tissue and the absence in normal tissue of a mycelium which is also found on certain trees and in some edible products imported from rural districts. Their presumption that this is the causative element in cancer seems to have some justification in view of results, observed by myself, of recent treatment by Dr. Nevil Leyton of cases of cancer, based on this hypothesis.

A Rare Complication of Labour

Dr. I. GORDON CAMERON (Kuala Lumpur, F.M.S.) writes: I recently attended a confinement which proceeded rapidly and normally till the child's head was born. I then found that the cord was tightly coiled twice round the child's neck. It was too tight to be released by the usual method of drawing loops over the head, so it had to be divided between forceps. On attempting to unwind it, I found that the cord was actually knotted, and a third pair of forceps had to be used to untie the knot. The child was then delivered rapidly and, to my relief, it breathed shortly afterwards. I have had one case with a short cord wound twice round the neck causing premature separation of the placenta, with concealed ante-partum haemorrhage, resulting in the death of the child, but I have never before come across a cord coiled twice round the neck and knotted. I wonder if a similar case has ever been reported in the medical literature.

The Occipito-posterior Case

Dr. ROBERT A. WELSH (Felton) writes: Bethel Solomons, in his *Epitome of Obstetrical Diagnosis*, says, "These [occipito-posterior presentations] are the bane of the practitioner outside Ireland. In Ireland patience is found to be the best treatment, and rotation usually occurs; this principle should apply also to other countries." He then goes on to say: "If spontaneous delivery does not occur some advise manual rotation, others forceps rotation, others manual rotation followed by forceps. We do none of these unless the head is low and rotates easily with the hand. If rotation is difficult we deliver as a persistent occipito-posterior with forceps."

The House of Dent

The publishing firm of J. M. Dent celebrated its jubilee two weeks ago with a dinner at Stationers' Hall, when Mr. Hugh R. Dent, son of the founder of the firm, presided. Those present were given a handsomely bound memorial volume entitled *The House of Dent*, which is a reissue of the *Memoirs of J. M. Dent* to which have been added four chapters bringing up to date the publishing activities of this well-known house during the past twelve years. It is a volume which can be warmly recommended to those who are interested in the writing and the making of books.

M & B 693.

We have received from Messrs. May and Baker, Limited, a copy of their booklet entitled *M & B 693: Biological and Biochemical Data*. We have previously referred in these columns to the results obtained from this product in the treatment of pneumococcal infection, and those who would like a copy of the booklet just issued, as well as a pamphlet on the use of M & B 693 in the treatment of pneumococcal infections, will receive them on application to the firm at Dagenham, England.

Disclaimer

Dr. S. LEVY writes: I should be glad if you would allow me to disclaim any responsibility for certain reports relating to the treatment of a patient in Tilbury Hospital which appeared in the daily Press. Neither this report, nor other reports concerning myself, were inspired by me, directly or indirectly.

KEY TO CURRENT MEDICAL LITERATURE

GENERAL JOURNALS

Deutsche Medizinische Wochenschrift

Berlin vol. 64 August 26, 1938

- Reflections on Indications for Radiological Examination. G. F. Haensch.—p. 1241.
New Aspects of Treatment of Disturbances of Circulatory System. C. Dienst.—p. 1247.
*Therapeutic Action of Anti-syphilitic Hyperthermia Induced by Physical Means. A. Beyersmans.—p. 1250.
Pupillotonia: Hereditary-degenerative Syndrome? G. Voss.—p. 1251.
In Search of Foreign Bodies. R. Paschke.—p. 1253.
Insulin Shock in Bronchial Asthma. H. Bartelheimer.—p. 1254.
Therapeutic Action of Radon Juice. W. Golder.—p. 1255.
Chaulmoogra Oil and Some of its Derivatives. A. Derner.—p. 1257.
Questions of Principle in Estimates of Internal Diseases. W. v. Drizahl.—p. 1258.

Physical Hyperthermia.—The conclusion drawn is that the high temperature artificially induced in the modern treatment of syphilis is itself the most important factor in the patient's recovery.

Irish Journal of Medical Science

Dublin vol. 6 September, 1938

- Clinical Diagnosis of Congenital Heart Disease. P. T. O'Tarrell.—p. 197.
Tuberculosis of Male Genital Tract. E. D'Arcy McCrea.—p. 614.
*Analeptics and Bragg-Paul Pulsator. R. H. Micks.—p. 629.

Analeptics and Bragg-Paul Pulsator.—The author discusses the mode of action of such analeptics as strychnine, coramine, camphor, cardiazol, and lobeline, and points out that the object of treatment with such drugs in cases of respiratory depression is the restoration of normal respiratory rhythm. In his opinion this can best be achieved by the use of an effective apparatus for performing artificial respiration; in the absence of a pulsator he regards stimulation by the inhalation of carbon dioxide as being more effective than the injection of any analeptic drug.

Journal of the American Medical Association

Chicago vol. 3 August 27, 1938

- Undergraduate Teaching of Obstetrics. E. Plass.—p. 761.
Health of the Migrant. W. Dickie.—p. 763.
Experimental Study of Behaviour of Sulphanilamide. F. Adair, H. Hestelune, and L. Hae.—p. 766.
Therapeutic Effectiveness and Toxicity of Sulphanilamide. E. Barnick, A. Brown, and F. Foster.—p. 770.

Duration of Small-pox Immunity. D. Loy and M. Husband.—p. 780.
Medical Education in United States and Canada.—p. 785.

Journal of the Royal Army Medical Corps

London vol. 71 September, 1938

- *Organization of Medical Services in Air Raid Precautions. E. M. Cowell.—p. 145.
Alienist's Point of View. G. W. Will.—p. 177.
Note on Typhoid and Paratyphoid Fever in Gallipoli Campaign (1915). A. Patrick.—p. 182.
Case of Leprosy in British Soldier. G. F. Harrison.—p. 194.
Neisseria catarrhalis Isolated from Blood Stream of Case of Benign Tertian Malaria. W. M. E. Anderson.—p. 199.

Medical Services in A.R.P.—This article is a comprehensive survey of the subject, and concludes by pointing out that the organization which will be required will involve a personnel of 1 in 30 of the total population of the country, of which personnel 1 in 50 should be fully trained medical men. Points which are discussed in particular detail concern an estimation of the casualties which are to be expected, the early issue of record cards to the population, and the first-aid treatment of casualties.

London vol. 71 October, 1938

- Effects of Mechanization on Evacuation. T. B. Nicholls.—p. 217.
War Neuroses. H. A. Sandford.—p. 222.
*Some Observations on *Salmonella* Flagellar Antigens. G. T. L. Archer.—p. 231.
Account of Six Solid Tumours of Jaws. S. H. Woods.—p. 224.
Transjordan Frontier Force. J. T. Tobiesen.—p. 255.
Case of Subcutaneous Rupture of Pancreas. G. Meulien.—p. 266.
Interesting Abnormality. K. Fletcher-Barrett.—p. 272.

***Salmonella* Flagellar Antigens.**—It has been shown that certain specific "H" *Salmonella* antigens may be "dominant" or "recessive" in culture. Evidence is also brought forward suggesting that in certain cultures one or more of the normal antigenic components of the group phase of the organisms present may be absent or greatly deficient. In view of these findings a modified method of classification is suggested.

 Imopagus. J. B. Vernaglla.—p. 266.
 Use of Prostaglandin as Preparation for Abdominal Roentgenography. M. J. Farrell.—p. 270.

Accidental Injury to Heart.—Bean reports four cases of severe injury to the heart resulting from attempts at therapy, two being cases of pericardial effusion where paracentesis was attempted and two cases of heart stoppage during anaesthesia in which an attempt was made to administer adrenaline intracardially. In the two former cases no attempt was made to remove the fluid from behind, where the danger to the heart is minimal. Both procedures are fraught with considerable risk unless adequate precautions are taken.

Boston vol. 219 September 1, 1938

 Nailing Fractured Neck of Femur with Aid of Fluoroscope. N. C. Browder.—p. 296
 Anal Fissure. G. S. Speare and R. E. Mabrey.—p. 302.
 Spivack Gastroscopy. F. H. Baehr and S. Treilung.—p. 305.

Nordisk Medicinsk Tidskrift

Stockholm vol. 15 August 27, 1938

- Neuropathological Communications. L. Sahlgren and H. Marcus.—p. 1335.
 *Aspiration Biopsy. P. A. Blinkenberg.—p. 1343
 Early Diagnosis of Schizophrenia. E. Goldkuhl.—p. 1346

Aspiration Biopsy.—Observation of 157 cases examined at the radium centres in Copenhagen and Odense has convinced Blinkenberg that aspiration biopsy is an easy method for obtaining tissues for microscopical examination. Positive results, without any complications, were obtained in about two-thirds of the punctures, the traumatic effect of which was negligible

1028 B

Policlinico

Rome vol. 45 August 29, 1938 (Sez. Prat.)

- Special Peptic Syndrome of Upper Abdomen (Acute Pancreatic Necrosis, Gastro-duodenal Ulcers, and Biliary Peritonitis). D. Sibilia.—p. 1594
 *Essential Angiospasmolytic Treatment in Infants. A. Andreoli and A. Cavallotti.—p. 1597.
 Avoidance of Gastro-intestinal Disturbances after Cholecystography. F. Cheva.—p. 1603.
 Arthropathic Psoriasis. G. Lionetti.—p. 1606.

Epilepsy in Children.—The authors discuss the evidence suggesting that cerebral ischaemia is one of the causes of "essential" epilepsy. They report eighteen cases, in children aged from 3 to 13, treated with considerable success by the protracted administration of extract of muscle, and they recommend combination of this with luminal therapy.

Rome vol. 45 September 5, 1938 (Sez. Prat.)

- *Treatment of Testicular Pain. G. Pieri.—p. 1629.
 Axillary Pulmonitis and Traumatic Factors in its Pathogenesis. F. De'Victoris-Medori.—p. 1636.

Testicular Pain.—Good results followed paravertebral injection of percaïne at the level of the second lumbar root in six acute cases of diverse causation. Three cases of chronic testicular pain were relieved by resection of the second lumbar ramus communicans.

Presse Médicale

Paris vol. 46 August 24, 1938

- *Lungs and Microbes. L. Binet and Ch. Jaulmes.—p. 1281.

Lungs and Microbes.—The authors have investigated the effect of adding various micro-organisms to the blood used in perfusing the aseptically isolated and rhythmically ventilated lungs of a dog. The organisms used included: *Strep. haemolyticus*, *Staph. aureus*, *B. erysipelatos suis*, *B. anthracis*, *B. pyocyaneus*, and enterococci. They found that the organisms gradually disappear from the circulating blood, whereas they remain or even increase in blood kept in an incubator. The addition of a suspension of carbon or Indian ink to the perfusing blood retards or inhibits the disappearance of the organisms.

Paris vol. 46 August 27, 1938

- *Classification of Nephritis. H. Chabanier and C. Lobo-Onell.—p. 1289.
 *Are the Polypeptides resulting from Tissue Proteolysis Toxic? P. Etienne-Martin.—p. 1292.

Classification of Nephritis.—As a result of eight years' work involving the investigation of close on 200 cases of kidney conditions of various kinds, the authors conclude that the most satisfactory classification up to date is that of Volhard and Fahr.

Toxicity of Polypeptides?—The author has been investigating the behaviour of the polypeptides resulting from the proteolysis of the tissues since 1930. He comes to the conclusion that they are only slightly toxic (if at all), and are probably not the cause of untoward occurrences attributed to them. Some diseases may give rise to polypeptidaemia, but polypeptidaemia does not give rise to disease.

Employment of Potassium Sodium Bicarbonate Solution in Treatment of Diabetic Coma. F. Kirk—p. 977.
Allergy and Gastric Ulcer. O. Sanders-Olesen—p. 978.

Pneumonia Studies.—This paper from the Danish State Serum Institute and the Sundby Hospital deals with patients treated between October, 1935, and May, 1938. Since November, 1937, the pneumococcal serum used has been derived almost exclusively from the rabbit. Such importance is attached to the type determination and serum treatment of pneumonia that Nissen recommends hospital treatment for as many as possible of such cases.

Diagnosis of Coronary Disease.—It is suggested that the diagnosis of myocardial infarction by x rays is possible in a high proportion of cases. Both the shape of the heart and the amplitude of the pulsation—the latter judged by fluoroscopy and kymography—are altered in the presence of infarction. The x-ray diagnosis was confirmed by the electrocardiogram in 75 per cent. of 140 patients studied, and of twelve cases which came to necropsy there was confirmation in ten. In one case necropsy revealed pulmonary thrombosis, the heart being normal. In this instance cardiac infarction had been suggested by the electrocardiogram but not by the x-ray findings.

Referred Pain of Cardiac Origin.—A new method for the diagnosis of angina pectoris was developed by the use of the "cuff test." The method consisted of producing ischaemia in the left arm for five minutes by raising the pressure in a blood-pressure cuff on the arm to 50 mm. Hg above the usual systolic pressure. In three cases in which the pain was referred to the right arm the result was positive with this arm but not with the left arm. The method proved to be successful in producing an anginal attack in nineteen out of twenty-four patients with angina pectoris. In eleven of these nitroglycerin, 1/150 grain, was given because of the severity of the pre-

Deaths during Week ended July 30, 1938: Deaths in Group of Large Cities in United States; Death Claims reported by Insurance Companies.—p. 1531.

Infectious Disease Returns: United States, Foreign, and Insular.—p. 1532.

Chronic Brucellosis.—In continuation of previous studies the authors give a critical account of the value of the usual tests for chronic brucellosis—namely, recovery of the organism from the patient, agglutination (1:40 being considered the minimum), the skin reaction, and the opsono-cytophagic reaction—with a view to ascertaining which should be considered conclusive and which confirmatory, taking into account the availability and technique of the different tests.

*Changes in Types of Visual Refractive Errors of Children A. Ciocco.—p. 1571

Deaths during Week ended August 13, 1938: Deaths in Group of Large Cities in United States; Death Claims reported by Insurance Companies.—p. 1579.

Infectious Disease Returns: United States, Foreign, and Insular.—p. 1580.

Refractive Errors in Children.—This study was undertaken to determine the frequency of the changes in refractive errors in children and the relation between the degree of error, visual acuity, and the changes due to age, with a view to formulating a programme for the conservation of eyesight in children. At an early age hyperopia is the more frequent error, but in older children myopia and corneal astigmatism are more common. On re-examination, after an interval of two and a half years, the frequency of simple hyperopia was reduced by 20 per cent., but the incidence of astigmatism was increased by 40 per cent. and of simple myopia by 70 per cent. In over 75 per cent. of those originally presenting refractive errors no change in type took place, and the chances of a change in type decreased as the child grew older. The trend of the changes noted was from simple myopia and hyperopia to astigmatism, and from astigmatism back to simple refractive error.

Washington vol. 53 September 9, 1938

*Percentage of Illnesses treated Surgically among 9,000 Families, based on Nation-wide Periodic Censuses, 1928-31. S. D. Collins.—p. 1593.

Miami Health Officer Acts to Prevent Introduction of Yellow Fever.—p. 1621.

Deaths during Week ended August 20, 1938: Deaths in Group of Large Cities in United States; Death Claims reported by Insurance Companies.—p. 1622.

Infectious Disease Returns: United States, Foreign, and Insular.—p. 1623.

Surgical Treatment in Families.—This contribution follows up a previous one (*Publ. Hlth. Rep., U.S.A., 53, 587*) dealing with surgical operations per 1,000 of population. In the present instance the surgical histories of nearly 9,000 families of various social orders were studied over a period of twelve consecutive months, and the results tabulated. It appears that the proportion of cases treated surgically increases with the family income, and there is more "surgery" in cities than in the rural areas; peak incidence occurs at ages 5 to 9 years, and again at 25 to 34 years. The frequency of different kinds of operation ran in the following order: non-venereal diseases of the male genitals (chiefly circumcision), 84 per cent.; mastoid diseases, 77 per cent.; cysts and tumours of the female genitals, 72 per cent.; other benign tumours, 63 per cent.; appendicitis, 58 per cent., salpingitis, 53 per cent. Considering the group as a whole, 7.6 per cent. of all cases were treated surgically; of those coming under the care of a doctor 10 per cent. were so treated; and of those referred to a hospital 60 per cent.

*Actions of Different Salts of Calcium on Leucocyte Response of Organism. G. Walthard.—p. 374

Pharmacology of Biphosphates. Neret-Cauchy.—p. 382

Actions of Calcium Salts.—By the injection of different preparations of calcium the author has induced in rabbits the appearance of a leucopenia with a relative lymphocytosis comparable with that which is seen in man in the early stages of typhoid fever and other infectious conditions. The most effective salts of calcium in this respect seem to be the chloride and the lactate; the least effective is calcium iodate.

*Relations between Diabetes Mellitus and Pulmonary Tuberculosis, and particularly Intestinal Tuberculosis. E. M. Müller.—p. 281.

*Bovine Infection in Pulmonary Tuberculosis and Possibility of Cultivation of Bovine Tubercle Bacillus. Maria Nuss.—p. 306.

Diabetes Mellitus and Tuberculosis.—This study is based on 125 patients suffering from diabetes and tuberculosis who were admitted to a tuberculosis hospital in Berlin between 1932 and 1937. They formed 1.7 per cent. of all the admissions. As in Berlin the proportion of diabetes is between 0.13 and 0.23 per cent., and that of people with active tuberculosis 0.3 per cent., it is clear that even in this era of insulin therapy the diabetic shows a raised susceptibility to the development of tuberculosis. Of these patients 61.6 per cent. are known to be dead, and on half of these (thirty-nine) a necropsy was performed. The predisposition to tuberculosis is less in the mildly diabetic and is greater in one not properly treated. Once tuberculosis develops the severity of the diabetes has little influence on the course of the tuberculous condition. The author could not confirm, either radiologically or at necropsy, the presence of a special form of "diabetic tuberculosis." The morbid anatomical studies support the author's previous finding that in diabetes suffering from pulmonary tuberculosis there is a notably lessened incidence of intestinal tuberculosis.

Pulmonary Tuberculosis of Bovine Origin.—Among 118 cases examined the author found two (1.7 per cent.) due to the bovine bacillus. The best culture medium was found to be that of Petragiani without glycerin.

Antivirin Nasal Jelly treats nasal congestion by a combined bacteriostatic and astringent action. 75% of the jelly—an increased proportion—consists of antivirus solution prepared from organisms commonly found in the naso-pharynx during attacks of the common cold. These antivirus factors prevent the growth of bacteria and stimulate local immunity. At the same time, the incorporation of 0.5% ephedrine relieves congestion and reduces irritating secretions. The jelly itself, a glycerin base, is pleasant and soothing. Unlike aqueous or oily solutions, it adheres and penetrates deeply and allows the antivirus to exert a prolonged anti-bacterial effect.

Used in the first stages of a cold, Antivirin Nasal Jelly helps to reduce the attack; while in the later stages it affords valuable relief.

FOOTWEAR FOR FOOT-FITNESS

This brief description of the principal features of Church's Arch-Moulded Shoes may be of interest to medical men.

1. The steel shank supporting the longitudinal arch is automatically fixed in its correct position.
2. The metatarsal arch is supported by a rubber pad, placed immediately behind the metatarsal heads.

3. The supports are built into the soles of the shoes, so that appearance is not affected in any way. There is a considerable choice of style.

4. The method of fitting ensures that the main part of the foot is closely and firmly fitted, full freedom being allowed for the toes.

5. There are upwards of 100 graded fittings available (including 6 different widths in every size and half size).

6. There are more than 300 shoe-men who are fully qualified to fit our shoes correctly, and to whom patients may be recommended with confidence.

We will gladly send full particulars to anyone interested.

Church's
ARCH-MOULDED
SHOES

CHURCH & CO., LTD., NORTHAMPTON

THERE is no reason, now, why you should be without the benefits which dependable quartz-mercury Ultra-Violet-Light equipment brings to both physician and patient.

Your investment in the entirely new, more efficient, lower priced Victor Model "F" Lamp would prove profitable both clinically and economically because:

1—There is such a wide variety of conditions in which Ultra-Violet irradiation can be employed as a basic or adjuvant therapeutic measure; and

2—The simplicity and sturdiness of the Victor Model "F" Lamp bespeak long, trouble-free life with minimum operating expense.

Send for abstracts from recent authoritative literature; read them and, also, an interesting booklet which describes fully this most recent development in the field of Ultra-Violet, the Victor Model "F" Lamp. Learn what a small financial outlay is required in order to have one of these splendid units installed in your consulting room. Simply detach and post the convenient coupon to-day.

An AMPLIVOX TO WEAR

With

CRYSTAL MICROPHONE
STANDARD BATTERIES
WEIGHING ONLY 1½ LBS.
AVAILABLE IN 3 DIFFERENT TONES

The introduction of the Model W AMPLIVOX has a special significance in view of the recent official medical recommendations for valve amplifier hearing aids. It effectively solves the problem of providing a high quality hearing aid with low upkeep costs, offering extreme simplicity and reliability to those who want the smallest possible instrument. It will go into a gentleman's hip pocket or lady's handbag with ease. It can readily be adapted to the Amplivox inductor system for telephone or theatre listening and so provides the most complete hearing aid ever made. I shall be glad to send you descriptive literature if this is not already in your possession.

IMPROVED MAW STEROTHERM HOT AIR ELECTRIC AUTOMATIC STERILIZER

(Patent No. 427541)

A thermostatically-controlled electrical apparatus for sterilizing Oils, Instruments, Glassware, Syringes, Dressings, and I.R. Gloves, etc., by means of Hot Air. Specially suitable for Hospitals, Nursing Homes, Doctors, Dentists, Veterinary Surgeons and Laboratory work.

- Compact, Reliable and Convenient (2 sizes).
- High quality White Cellulose finish.
- Efficiently lagged.
- Polished Aluminium Heat Reflecting Lining.
- Easily read Thermometer.
- Automatic regulation of temperature.

- No supervision necessary in use.
- Very small current consumption.
- Articles remain sterile until required as closure is Bacteria-proof.
- Can be plugged in anywhere the voltage is suitable.
- Supplied in any voltage, complete with fittings.

Maw Sterotherms have already been supplied to a number of prominent London and Provincial Hospitals, the Crown Agents and various Councils, where they are giving every satisfaction.

Large size £22

In acting as an executor or trustee, the Westminster Bank aims at putting itself in the position of a private trustee. It is therefore its practice to employ the family solicitor, if there is one, or any other solicitor the client may name; by such means the Bank succeeds in combining domestic tradition with business efficiency. A book showing the advantages of corporate executorship and the terms of appointment may be had at any branch or at the branch situated in B.M.A. House, Tavistock Square, W.C. 1

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President. THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D. M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent Telephone No. 2356 and 2357 (Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES FOR NERVOUS AND MENTAL DISORDERS.

This Hospital has every facility for complete investigation of the above conditions, and provides all forms of modern treatment including psychotherapy, physiotherapy, occupational and recreational therapy. Cases of alcoholism and drug addiction are admitted. The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy (swimming bath, prolonged baths, Scotch and Vichy douches, Plombières treatment, electric and Turkish bath cabinets, etc.). There is a fully equipped gymnasium under qualified instructors. Facilities are provided under special recreational therapists for all indoor and outdoor games, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens.

The Hospital has its own Cinema, Library and Hairdressing Saloon. Terms include regular motor drives.

Private rooms, suites or villas are available and special nurses can be provided.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country and include an extensive farm (11 held), gardens and orchards.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week. Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Superintendent: P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law.
July 1st. Tel: Dumfries 1119.

Secretary

MIDDLEBROUGH EDUCATION COMMITTEE.

APPOINTMENT OF SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified men, who have had experience of School Medical work, for the post of Senior Assistant School Medical Officer in connection with the Medical Inspection and Treatment of School Children, and such other duties as may be required by the Education Committee. The person appointed will be responsible to the School Medical Officer.

Commencing salary £200 per annum, rising by annual increments of £25 to £250 per annum, there by the annual increments of £50 to a maximum salary of £300 per annum.

The successful candidate will be required to devote his whole time to the duties of the office. The appointment will be subject to two calendar months' notice on either side, such notice during the last day of any calendar month. Candidates who must have had experience in the work of the School Medical Service, and preference will be given to candidates who have had experience of Refraction work and who are recognized by the Board of Education in connection with certification under the Mental Deficiency and Other Acts.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the successful candidate passing satisfactorily a medical examination.

Forms of application may be obtained from the Director of Education on receipt of a stamped addressed foolscap envelope and these should be returned to the Director of Education, Education Office, Middlebrough, not later than Saturday, November 26th, 1938.

Canvassing in any form will be disqualifying. Town Clerk's Office, Preston Kitchen, Middlebrough, Town Clerk. November 7th, 1938.

COUNTY OF BRECON ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Assistant (male or female) Medical Officer for the County of Brecon, at a commencing salary of £500 per annum, rising by annual increments of £50 to a maximum of £600 per annum, with travelling and subsistence allowances according to the County Scale.

Applicants must be registered Medical Practitioners with at least three years' practical experience in their profession, competent to assist the County Medical Officer in the general administration of his Department, particularly in Ante-natal Clinic, Refraction work, examination of Blind Persons under the Blind Persons Acts, School Medical Inspection and Maternity and Child Welfare work, and must either possess special experience of practical midwifery and ante-natal work, or have, prior to April 1930, held the appointment of Medical Officer of an Ante-natal Clinic with the approval of the Minister of Health.

Knowledge of Welsh desirable, and ability to drive a car essential.

The person appointed must be prepared to reside in or near to Brecon, and to be under the direction of the County Medical Officer of Health, will be required to perform such duties as the Council may direct, and to devote the whole of his or her time to the duties.

The appointment will be terminable by three calendar months' notice on either side. Canvassing members of the Council, either directly or indirectly, will be a disqualification.

The post is designated as an established post under the Local Government and Other Officers' Superannuation Act, 1922.

Applications must be made on forms which can be obtained from the undersigned accompanied by three copies of three recent testimonials, and must be received by me not later than November 25th, 1938.

W. F. W. BETENSON, County Medical Officer of Health, County Health Offices, The Watton, Brecon, October 29th, 1938.

CORPORATION OF DUNDEE PUBLIC HEALTH DEPARTMENT. OBSTETRICIAN AND GYNAECOLOGIST

Applications are invited from registered Medical Practitioners for the appointment of Obstetrician and Gynaecologist (part-time) to the Public Health Department (Maryfield Hospital, etc.). Salary £450 per annum.

A statement outlining the conditions of appointment and the nature of the duties may be had on application to the Medical Officer of Health, Central Public Health Office, 9, West Bell Street, Dundee. A copy of this statement should be obtained by intending applicants.

Applications, giving full particulars regarding qualifications and experience, must reach the undersigned on or before Tuesday, November 22nd, 1938. City Chambers, Dundee, DAVID LATTO, Town Clerk, October 28th, 1938.

LIVERPOOL COUNTY BOROUGH. LOCAL EDUCATION AUTHORITY. ASSISTANT SCHOOL MEDICAL OFFICER (Male)

Applications are invited for a male Assistant School Medical Officer to the Department of the Medical Officer to the Local Education Authority, at a salary of £500 per annum, rising by annual increments of £25 to £600 per annum.

Where the successful candidate holds a similar appointment under another Local Education Authority, and receives a salary in excess of the advertised minimum, a commensurate salary of not less than the salary which the candidate is receiving under his existing appointment, not exceeding the maximum under the Liverpool Scale, may be paid.

Candidates must be registered medical practitioners, and must have had at least three years' experience.

The Officer appointed will be required to reside within the city, and devote whole-time service to the Local Education Authority under the direction of the Medical Officer to the Local Education Authority, and will not be allowed to undertake any private practice.

The appointment will be subject to the Standing Orders of the City Council and to the Local Government Superannuation Act, 1937.

Form of application, which may be obtained by forwarding a stamped addressed foolscap envelope, should be returned, together with copies of three recent testimonials, to the undersigned not later than November 24th, 1938, and endorsed "Assistant School Medical Officer".

The canvassing of Members of the Education Committee or of the City Council is strictly prohibited, and will be considered a disqualification. Municipal Buildings, Liverpool, 2, Town Clerk and Clerk to the Local Education Authority, November 11th, 1938.

SURREY COUNTY COUNCIL ASSISTANT MEDICAL OFFICERS

Applications are invited for the appointment of Assistant Medical Officers. Applicants must possess a qualification in Public Health. The main duties will be in connection with the School Medical and Maternity and Child Welfare Services, but the officers appointed will be required to undertake such other Public Health duties as may be allocated to them. They will be on the staff of the County Medical Officer of Health, must reside in the County of Surrey, and devote their whole time to the work.

Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointments will be subject to the approval of the Ministry of Health and the Board of Education. To the successful candidates passing a medical examination, to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the Standing Regulations of the Council which provide, *inter alia*, that appointment may be determined at any time by three months' notice.

Applications, stating age, qualifications and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained and to whom any inquiries relating to the appointment should be addressed.

Last day for receipt of application, Wednesday November 16th, 1938.

Canvassing, directly or indirectly will be disqualifying. DUDLEY AUKLAND, Clerk of the County Council.

County Hall Kingston-upon-Thames, November 1st, 1938.

COUNTY BOROUGH OF HUDDERSFIELD APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH

Applications are invited from registered Medical Practitioners (Males) who have had special experience of ante-natal work and in the care of infants. Salary £500-£25-£700 initial salary according to experience. The doctor appointed will be required to reside in the Municipal Maternity Home where the extensions in progress at present have been completed. A deduction will then be made from the salary for board, etc.

The post will be designated under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination before being appointed to the position.

Applications, stating age, full particulars regarding training, qualifications, and appointments held since qualification, should be forwarded to the Medical Officer of Health, Public Health Department, Huddersfield, along with copies of two recent testimonials, as at or before Thursday, November 17th, 1938.

Application forms are not provided. SAMUEL PROCTER, Town Clerk, Town Hall, Huddersfield, November, 1938.

COUNTY BOROUGH OF BLACKBURN. PUBLIC ASSISTANCE DEPARTMENT. RESIDENT JUNIOR ASSISTANT MEDICAL OFFICER

Applications are invited from Medical Practitioners (male) for the appointment of a Resident Junior Assistant Medical Officer at Queen's Park Hospital and Institution.

The Staff consists of a Resident Medical Officer, a Resident Assistant Medical Officer, a Consulting Surgeon, a Laboratory Assistant, and an X-ray Attendant.

There is a separate Infirmary, a separate Maternity Block, and a separate Hospital for children, and there is opportunity for experience in all departments including Medical, Surgical, and Midwifery cases. An X-ray apparatus is installed.

The person appointed will be required to devote his whole time to the duties, and also to act as may be directed by the Resident Medical Officer. The appointment will be limited to a term not exceeding one year. Salary at the rate of £200 per annum, together with board, apartments and attendance.

Applications, stating age, qualifications and experience, accompanied by copies of not more than three recent testimonials, must be sent to the Public Assistance Officer, Public Assistance Office, Cardwell Place, Blackburn.

Town Hall, Blackburn, CHAS. S. ROBINSON, Town Clerk, October 31st, 1938.

GENERAL POST OFFICE. HEADQUARTERS MEDICAL BRANCH (Male Staff)

There is a vacancy for a MALE ASSISTANT MEDICAL OFFICER in the Headquarters Medical Branch. The appointment is pensionable and carries a salary which commences at £500 a year, and rises by annual increments of £25 to a maximum of £600 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject, and the child of a person who is, or was at the time of death, a British subject. Preference will be given to candidates under 30 who have held one or more Hospital appointments. The successful candidate will not be allowed to engage in private practice in his official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer, General Post Office, London, E.C.1, not later than December 3rd, 1938. Political influence should not be sought in support of applications. It would prejudice rather than assist the candidate.

The Male Medical Staff at Headquarters consists at present of a Chief Medical Officer, a Second Medical Officer, and four Assistant Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interviews in London at their own expense.

CITY OF MANCHESTER CRUMPSALL HOSPITAL (1543 Beds) (Recognized under Regulation for the F.R.C.S.)

The Public Health Committee invites applications from registered medical men for the post of RESIDENT ASSISTANT MEDICAL OFFICER at the above-named Hospital.

The salary for the appointment is £200 per annum, with board, residence and laundry in addition, subject to the Manchester Corporation conditions of service.

The appointment will be made in the first instance for a period of six months, renewable for a further six months, but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Town Hall, Manchester, 2, and applications for the post must be received by him not later than November 16th, 1938.

Town Hall, Manchester, 2, R. H. ADCOCK, Town Clerk, October 31st, 1938.

MIDDLESEX COUNTY COUNCIL WEST MIDDLESEX COUNTY HOSPITAL Twickenham Road, Isleworth

Additional VISITING OPHTHALMIC SURGEON required—must be F.R.C.S. (Ed.) or recognized University Ophthalmology Diploma and registered Medical Practitioner practising ophthalmology.

Fee three guineas per session. One session per week. Non-pensionable post, subject to three months' notice.

Written application, giving details of age, qualifications and experience, should be sent to the undersigned in envelope endorsed "O.P.—Ophthalmology" by November 19th, 1938.

C. W. RADCLIFFE, Clerk of the County Council, Guildhall, Westminster, S.W.1, October 29th, 1938.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than November 21st, 1938.

ROYAL NAVAL DENTAL SERVICE

Applications are invited for appointment to commissions as DENTAL OFFICERS in the ROYAL NAVY.

Candidates who must be British subjects below the age of 28 years, must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dentists Acts or Medical Acts. Unmarried candidates are preferred. No examination in professional subjects will be held but candidates will be required to attend at the Admiralty for interview, and for physical examination as to their fitness for service in any part of the world.

Successful candidates will be appointed to short service commissions as Surgeon Lieutenants (D) and will receive a grant of £50 towards the cost of providing the necessary uniform on entry. Vacancies in the permanent list will be filled by selection from among officers holding short service commissions who desire to make the Royal Naval Dental Service their permanent career. Officers not transferred to the Permanent List will, on the termination of their short service engagement after six years' service, be eligible for a gratuity of £1,000.

Opportunities are available for officers on the permanent list for postgraduate study. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances. Naval Dental Officers are included in the Scheme for Marriage Allowance under the same conditions as for other Naval Officers.

Application forms and copies of the regulations for entry and conditions of service, rates of pay and allowances, etc., may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of Dental Schools.

BOROUGH OF LUDMORDEN.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited for the position of Medical Officer of Health and Superintendent of Infectious Diseases Hospital. Salary £100 per annum, and maximum allowance of £70 per annum. The appointment is subject to the Local Government and other Officers' Superannuation Act, 1922.

Applicants should send age, qualifications, and experience with copies of not more than three recent testimonials to reach me on or before November 21st, 1938, in envelopes endorsed "Medical Officer."

Medical Officer, HERB GARRATT, Town Clerk.

THE ARMY DENTAL CORPS.

Applications are invited from DENTAL SURGEONS for appointment to commissions in the ARMY DENTAL CORPS.

Candidates, who should not be over 28 years of age, will for the present be selected for commissions without competitive examination, but will be required to present themselves in London for interview and physical examination. They must hold the degree or diploma of a British University or College of Surgeons, and be registered under the Dentists' Acts or Medical Acts.

Successful candidates will, in the first instance, be given short service commissions for six years, at the end of which period they will retire with a gratuity of £1,000, unless they have been granted permanent commissions. Permanent commissions will be given to officers selected from among those who wish to make the Army their permanent career.

Particulars, including Regulations for Admission, pay and allowances, and forms of application may be obtained on request, either in writing or in person, to the Director, Army Dental Service, The War Office, London, S.W.1.

METROPOLITAN BOROUGH OF LAMBETH.

DEPUTY MEDICAL OFFICER OF HEALTH.

The Lambeth Borough Council invite applications from fully qualified medical practitioners for the appointment of Deputy Medical Officer of Health for the Borough at an inclusive salary of £840 per annum, rising by annual increments of £40 to a maximum of £960 per annum.

Candidates must not be more than forty years of age on November 17th, 1938, and must possess the qualifications prescribed by the Public Health (London) Act, 1936, and the Sanitary Officers Order, 1926. The gentleman appointed will be required to devote the whole of his time to the duties of the office, to contribute to the Council's Superannuation Fund, and to submit himself to the Council's Doctor for examination, the appointment being subject to such Doctor's report being satisfactory. The appointment will also be subject to the approval of the Minister of Health.

Applications, on forms to be obtained from the undersigned, endorsed "Deputy Medical Officer" accompanied by copies of three testimonials of recent date, are to be delivered by post on Monday, November 21st, 1938.

Canvassing either directly or indirectly, will disqualify a candidate.

Lambeth Town Hall, Brixton Hill S.W.2
October 25th, 1938.

O. L. ROBERTS,
Town Clerk

EAST SUSSEX COUNTY COUNCIL.

SOUTHLANDS HOSPITAL, SHOREHAM-BY-SEA.

ASSISTANT RESIDENT MEDICAL OFFICER

Applications are invited from fully qualified male registered Medical Practitioners (unmarried) for the post of Assistant Resident Medical Officer at Southlands Hospital, Shoreham-by-Sea, near Brighton. The appointment is for one year. Salary £300 per annum, with board, residence, and laundry. Preference will be given to candidates who have had special experience in Obstetrics and Gynaecology. The Hospital (350 beds) is a general hospital, under the administration of the East Sussex County Council. The duties of the post are mainly concerned with obstetrical care (forty maternity beds), but there are general duties in addition.

Application should be made on a form obtainable from the undersigned at the County Hall, Lewes, and must be returned to him by Saturday, November 19th. It is desired that the selected applicant shall commence duty on January 1st, 1939.

County Hall, W. R. EDWARDS,
Lewes, Deputy Clerk of the County Council
October 28th, 1938.

ROWLEY REGIS BOROUGH COUNCIL.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Female).

The Council of the Borough of Rowley Regis invite applications for the above whole-time appointment from duly qualified registered Medical Practitioners. It is essential that the Officer appointed should have had experience in Maternity and Child Welfare work. The salary will be £500 and will rise, subject to satisfactory service, by annual increments of £25 to £700 per annum, travelling expenses, in accordance with the Council's scale, will be allowed. The appointment is subject to the Local Government Officers' Superannuation Act, 1922.

Candidates must apply on the prescribed form which can be obtained from Dr. FRANK AKER, Medical Officer of Health, Haden Hill Park (Off. 2), Old Hill, Staffs.

Applications, together with copies of not more than three testimonials, must be received by the undersigned not later than Saturday, November 26th, 1938.

Council House, C. DUCKLEY,
Old Hill, Staffs. Town Clerk

INDIAN MEDICAL SERVICE

RECRUITMENT OF EUROPEAN OFFICERS

Applications are invited from Medical Men for Permanent Commissions in His Majesty's Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or of £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

British subjects of pure European descent who are under 32 years of age who are registered under the Medical Acts in force in Great Britain and Northern Ireland are eligible to apply.

CAREERS.

The Indian Medical Service offers a permanent career with wide opportunities of medical experience, including clinical, preventive, specialist and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian Service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of Civil Officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

RATES OF PAY.

| Years of Service | Rank | Basic Pay Rs. per month | Overseas Pay, £ per month | Total £ per annum |
|------------------|------------|-------------------------------|---------------------------------|-------------------------|
| 1 | Lieutenant | 450 | 15 | 585 |
| 2 | Captain | 500 | 25 | 750 |
| 3 | " | 550 | 25 | 795 |
| 4 | " | 550 | 25 | 795 |
| 5 | " | 600 | 25 | 840 |
| 6 | " | 600 | 30 | 900 |
| 7 | " | 700 | 30 | 990 |
| 8 | " | 700 | 35 | 1050 |
| 9 | " | 700 | 35 | 1050 |
| 10 | " | 800 | 35 | 1140 |
| 11 | Major | 800 | 40 | 1200 |
| 12 | " | 800 | 40 | 1200 |
| 13 | " | 800 | 40 | 1200 |
| 14 | " | 800 | 40 | 1200 |
| 15 | " | 800 | 40 | 1200 |
| 16 | " | 950 | 40 | 1335 |
| 17 | " | 950 | 40 | 1335 |
| 18 | " | 950 | 40 | 1335 |
| 19 | " | 1100 | 40 | 1470 |
| 20 | " | 1100 | 40 | 1470 |
| 21 | Lieut. Col | 1350 | 40 | 1695 |
| 22 | " | 1350 | 40 | 1695 |
| 23 | " | 1350 | 40 | 1695 |
| 24 | " | 1500 | 40 | 1830 |
| 25 | " | 1500 | 40 | 1830 |

Note.—(1) The rupee is at present stabilized at a rate equivalent to 1s. 6d.

(2) An officer promoted to the rank of Lieut.-Colonel before completion of 20 years' service will receive pay at the rate of Rs. 1219 per mensem (basic) plus £40 per month overseas pay.

Extras—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

· ANTEDATES IN COMMISSION.

Candidates possessing certain higher medical qualifications or holding the Diploma in Public Health may be granted an antedate in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate. Persons holding or about to hold resident posts at recognized

hospitals may be seconded in those posts for a period. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to 18 months.

OUTFIT ALLOWANCE.

Officers on appointment will receive an allowance of £75 towards the cost of outfit.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice so long as it does not interfere with their proper duties.

LEAVE

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed twelve months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a postgraduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America and Canada, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pensions are as follows:— Per annum.

| After 17 years' service for pension ... | ... | £372 | 0s. |
|---|-----|------|------|
| 18 | 18 | £400 | 0s. |
| 19 | 19 | £428 | 0s. |
| 20 | 20 | £465 | 0s. |
| 21 | 21 | £502 | 0s. |
| 22 | 22 | £539 | 10s. |
| 23 | 23 | £576 | 10s. |
| 24 | 24 | £614 | 0s. |
| 25 | 25 | £651 | 0s. |
| 26 | 26 | £697 | 10s. |
| 27 | 27 | £744 | 0s. |

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of prevailing charges. Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately three months, prior to their embarkation for India on first appointment. Information as to the rates of pay admissible during this period and subsequently up to arrival in India is contained in the memorandum referred to below.

A memorandum giving full details regarding these appointments and forms of application may be obtained from the UNDER-SECRETARY OF STATE FOR INDIA, MILITARY DEPARTMENT, INDIA OFFICE, LONDON, S.W. 1. The Selection Committee will meet at the India Office on 6th December, 1938, and the selected candidates, unless seconded for hospital appointment, will be required to join a course of instruction commencing on 1st January, 1939, prior to sailing for India in April, 1939.

Applications should reach the India Office as soon as possible.
INDIA OFFICE. NOVEMBER, 1938.

BOROUGH OF WIMBLEDON

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Male)

Applications are invited for the above appointment from qualified and registered medical practitioners under 35 years of age having at least three years' experience since qualification. Applicants should possess the D.P.H., and experience of School Medical work and general public health work is necessary.

The Officer appointed will be required to reside in the Borough, to devote his whole time to his official duties and to work under the direction of the Council's Medical Officer of Health.

The commencing salary is £600, rising by annual increments of £25 to a maximum of £700 per annum. The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to the passing of a medical examination.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Wimbledon, to whom they must be returned, with copies of three recent testimonials, not later than last post on Monday, November 21st.

HERBERT EMERSON SMITH, LL.B.,
Town Hall, Wimbledon S.W.19 Town Clerk
November 1st, 1938

CITY OF BIRMINGHAM

ASSISTANT MEDICAL OFFICER OF HEALTH

The Public Health and Maternity and Child Welfare Committee invite applications for the post of whole-time Assistant Medical Officer of Health for general, and mainly administrative, public health duties. Candidates must be qualified medical practitioners and hold a Diploma in Public Health.

The successful candidate will be required to pass an approved medical examination, to contribute to the superannuation scheme, established under the Local Government and Other Officers' Superannuation Act, 1922, as amended by Section 82 of the Birmingham Corporation Act, 1915—Annuities for Widows—and, if under 30 years of age, to join the Birmingham Municipal Officers' Widows and Orphans' Pensions Scheme.

The appointment will be terminable by one month's notice on either side. Salary £600 per annum, rising by £25 annually to £600.

Applications, endorsed "Assistant Medical Officer of Health" and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, The Council House, Birmingham, 3, and returned to him by Saturday, November 26th, 1938.

Conveying, directly or indirectly, is prohibited and will result in disqualification.
F. H. C. WILTSHIRE,
Town Clerk

BURY AND DISTRICT JOINT HOSPITAL BOARD

RESIDENT ASSISTANT TO THE MEDICAL SUPERINTENDENT.

Wanted, an Assistant to the Medical Superintendent of the Institutions of the Joint Board. These consist of a Fever Hospital (100 beds), a Sanatorium (70 beds), and a Small-pox Hospital. Candidates must be registered medical practitioners. The appointment is a whole-time one, and the person appointed will assist the Medical Superintendent generally and as he requires. Preference will be given to male unmarried candidates with hospital experience and special experience in pulmonary tuberculosis.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Commencing salary £400 per annum, with £25 increase at the end of the first year and a further £25 increase at the end of the second year, with board, washing and lodging.

Applications, stating age, qualifications and experience, together with testimonials, to be sent to me on or before November 15th, 1938.

Horoby Buildings, F. A. BRADLEY,
The Rock Clerk to the Board
Bury, Lancashire

GLAMORGAN COUNTY COUNCIL.

APPOINTMENT OF TEMPORARY MEDICAL OFFICERS.

TWO ASSISTANT MEDICAL OFFICERS (one man, one woman) are required for temporary service in the Public Health Department of the Glamorgan County Council. Preference will be given to those who have held resident appointments. Salary at the rate of £500 per annum, with travelling expenses and allowances on the County Scale.

Applications for the appointments, stating age and qualifications, and accompanied by copies of not more than three recent testimonials, should be sent immediately to the County Medical Officer, Dr. E. COLSTON WILLIAMS, Glamorgan County Hall Cardiff.

HENRY ROWLAND,
Clerk of the County Council,
Glamorgan County Hall,
Cardiff, November 7th, 1938.

COUNTY BOROUGH OF BARROW-IN-FURNESS

Applications are invited for the appointment of MEDICAL OFFICER OF HEALTH and PORT MEDICAL OFFICER of the Borough, subject to the provisions of the Sanitary Officers' Order, 1926, and the Local Government Act, 1933.

Candidates must not be more than 42 years of age.

The person appointed will be required to perform all the duties of a Medical Officer of Health under relevant Acts and Orders, to act as School Medical Officer for the Borough, Administrative, Infectious Diseases Officer, and Superintendent of the work of the Maternity and Child Welfare Service. He will also be required to act as Medical Superintendent of the Devonshire Road Isolation and Infectious Hospital.

The person appointed must reside within the Borough, devote his whole time to the duties of the office, and not engage in private practice.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The successful candidate will be required to pass a medical examination.

The salary to cover all duties will commence at the rate of £700 per annum, rising, subject to satisfactory service, by annual increments of £50 to a maximum of £1,050 per annum. A motor car allowance of £50 per annum will be granted.

Applications, endorsed "Medical Officer of Health," stating age, qualifications and experience, and accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than Wednesday, November 23rd, 1938.

Conveying, directly or indirectly, is prohibited and will result in disqualification.
Town Hall W. LAWRENCE ALLEN,
Barrow-in-Furness Town Clerk

WIRRAL JOINT HOSPITAL BOARD

CHATHAMBRIDGE ISOLATION HOSPITAL (100 Beds)

The Wirral Joint Hospital Board invite applications from registered practitioners for the post of RESIDENT ASSISTANT MEDICAL OFFICER at the above-named Hospital.

Preference will be given to applicants who have had experience in bacteriology.

The Hospital is situated within easy distance of the Liverpool Medical School, and time will be allowed, when the work of the Hospital permits, for attendance at D.P.H. or other higher qualification classes.

The appointment is for one year only and is not renewable.
Salary £200 per annum, with board, residence, and laundry.

Duties to begin February 1st, 1939.
Application, stating age, qualifications, etc., and accompanied by copies of recent testimonials, to be made not later than December 15th, 1938, to
DAVID HUNTING,
Clerk to the Joint Hospital Board
61, Hamilton Square,
Liverpool

Suitable house available with 5 bedrooms, etc. Premium 2 years' purchase. Ingoing partner must be experienced and energetic worker.
34. MANCHESTER.—Very old-established middle- and working-class PRACTICE averaging for last 3 years £1,350 p.a. Panel of 840. Appointments about £180 p.a. Fee from 3/6. House with 3 bedrooms, etc., garden, garage, electric light. Price freehold £950. Premium for quick sale, 1½ years' purchase, part by instalments.
35. LONDON, EAST.—Old-established mixed-class PRACTICE averaging about £2,700 p.a., including panel of about 1,300, and increasing. Separate surgery premises. Premium 2 years' purchase.
36. LONDON, N.W.—GROWING RESIDENTIAL DISTRICT.—PARTNERSHIP.—Guaranteed share in rapidly expanding Practice producing to commence about £500 p.a. with increase later. Suitable detached house on rental at £52 p.a. Ingoing partner must be experienced and energetic.
37. YORKS.—COUNTRY PRACTICE.—Old-established, income about £1,030 p.a. with scope for increase. About £350 of present income is derived from panel of some 500 patients. Good freehold house with ample accommodation, garden and garage. Price for practice and house £3,600, of which about £1,900 may be left on mortgage.
38. GLDS.—NEAR WYE VALLEY.—Very sound PRACTICE producing about £1,300 p.a., including panel of 1,150 patients and appointments worth about £80 p.a. Low expenses. Detached house with large garden, 5 bedrooms, etc. Freehold. Premium £2,200 purchase.
39. FAVOURITE SOUTH COAST RESORT.—Private and better-class PRACTICE averaging over £1,000 p.a. Minimum fee 5/-. No dispensing. Scope for panel if desired. Modernized house with ample accommodation. Premium £1,000.
40. MIDLANDS.—GOOD RESIDENTIAL COUNTRY DISTRICT.—Compact PRACTICE at present producing about £750 p.a., but capable of considerable expansion. Choice of 2 houses. Moderate premium for quick sale. Vendor retiring through ill-health.

ASSISTANTS REQUIRED.—Several good vacancies. Full particulars on application.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

GLYCURRANT COUGH LINCTUS

is a new expectorant and sedative preparation, particularly suited to dry coughs, such as that of chronic bronchitis. Its carefully planned composition includes the juice of ripe black currants, an agent which is well known for its soothing effect on the pharynx, and which gives a distinctive, delicious flavour to the mixture.

In bottles at 1/6 and 2/9

Descriptive literature and clinical trial sample, will be sent on application.

REDUCED TOXICITY

in anti-bacterial therapy is an important consideration. Abundant clinical evidence has established RUBIAZOL as a highly active and safe remedy for all hæmolytic streptococcal infections.

ADVANTAGES INCLUDE:—

- The most acute cases respond to a daily dose of 2 grammes (30 grains).
- No clinical manifestations of toxicity noted after three years' trial on the Continent.
- Is effective in prophylaxis and treatment.

HENRY KIMPTON'S PUBLICATIONS**NEW BOOK****JUST READY****REFRACTION OF THE EYE**

By ALFRED COWAN, M.D.

Royal Octavo, 319 pages, with 172 Engravings and 5 Coloured Plates.

Cloth

Price 21s. net. (Postage 6d.)

This book not only clarifies the subject of refraction, but it will make far more effective the use of the various instruments and charts involved in this field. The methods of determining the refraction of the eye and the management and optical treatment of ametropia are fully covered.

NEW BOOK**JUST READY****PRACTICAL MICROBIOLOGY AND PUBLIC HEALTH**

By WILLIAM BARNARD SHARP, M.D., Ph.D.

Octavo, 492 pages, with 125 Illustrations.

Cloth.

Price 18s. net. (Postage 6d.)

This book is intended for students of medicine, public health and general bacteriology. It is designed to aid the student in organization, interpretation and systematic record of data from laboratory and field. Experiments are largely those that usage has tended to standardize.

NEW BOOK**READY NOW****ATLAS OF SKELETAL MATURATION**

By T. WINGATE TODD, M.B., Ch.B.(Manc'h.), F.R.C.S.(Eng.).

Demy Quarto, 75 Radiographic Plates of the Hand.

Cloth.

Price 31s. 6d. net. (Postage 9d.)

This atlas contains 75 half-tones of roentgenograms selected as typical of the successive stages in ossification in the hand of boys and girls from three months until the date in adolescence when all epiphyses are united. There are more than a hundred pages of text dealing with general problems involved in the study and specific problems of the hand.

NEW BOOK**JUST READY****APPLIED ANATOMY**

Functional and Topographical

By ROBERT H. MILLER, M.D.

Royal Octavo, 484 pages, with 55 Engravings and 16 Coloured Plates.

Cloth.

Price 30s. net. (Postage 9d.)

This work is designed to enable the student and physician to correlate the many facts gained by observation and to apply them to the dynamics and function of the living body. It is a practical summary of the essentials of anatomy that will be found increasingly useful as a reference work.

NEW (SEVENTH) EDITION**JUST READY****DISEASES OF THE NOSE, THROAT AND EAR**

Medical and Surgical.

By WILLIAM LINCOLN BALLENGER, M.D., F.A.C.S. and HOWARD CHARLES BALLENGER, M.D., F.A.C.S.

FUNDAMENTALS OF INTERNAL MEDICINE

By W. M. YATER, M.D., and Collaborators.

The essentials of internal medicine—that basic knowledge of the subject which every practitioner and student should have at his fingertips. The classifications of diseases, about which so much difference of opinion exists, the simplest and most practical method has invariably been the one chosen. An excellent section on dietetics will prove of great value and the 255 illustrations, selected by Dr. Yater for their value as a diagnostic aid and placed appropriately throughout the volume, are one of its most helpful features. 1021 pages. 35/-

A TEXTBOOK OF MEDICAL BACTERIOLOGY

By D. L. BELDING, M.D., and A. T. MARSTON, Ph.D.

Presents the knowledge of bacteriology necessary to the medical practitioner and student. It contains only those of the most recent discoveries, the validity of which has been definitely ascertained. Medical bacteriology has been orientated to general bacteriology and emphasis is placed upon its application to public health and preventive medicine. 392 pages. 43 Figures, 1 Coloured Plate and Bacterial Chart. 46 Tables. 21/-

ESSENTIALS OF PATHOLOGY

By L. W. SMITH, M.D., and E. S. GAULT, M.D.

A remarkable text on pathology—one of the first to employ the case history method of presenting the subject. Besides the photomicrographs and gross pathological pictures, the authors have included a number of roentgenograms for demonstration of pathological alteration in the form and functional capacity of an organ. The 12 full-page colour plates are the work of Valentine and Pictet. 886 pages. 160 full-page Plates. 35/-

D. APPLETON-CENTURY COMPANY, 34 BEDFORD STREET, LONDON

ILLUSTRATIVE ELECTROCARDIOGRAPHY

By J. H. BAINTON, M.D., and J. BURSTEIN, M.D.

"Considerable skill in the interpretation of electrocardiographic records could be easily achieved by a close study of this volume. It is attractively produced and the price is modest for such a profusely illustrated book."

—Practitioner 21/-

258 pages

100 Plates

A CROSS-SECTION ANATOMY

By ALBERT C. EYCLES HYMER, M.D., and D. M. SCHOEMAKER, M.D.; Average Position of Organs, from Eleven Reconstructions, by PETER POTTER, M.D.; Sections of the Female Pelvis, by CARROLL SMITH, M.D.; Drawings by TOM JONES.

Includes 113 cross-sections of the human body, four-fifths life-size. These, together with 14 key figures which interpret the cross-section plates by indicating on the body surfaces the levels at which the sections were made, reveal the anatomy of the various levels of the body with exactness.

One large folio volume, 11 1/2" x 15". 215 pages. 130 Illustrations. 50/-

SYMPTOM DIAGNOSIS

By W. M. BARTON, M.D., and W. M. YATER, M.D.

The reader will quickly be enabled to locate the important symptoms of any disease. The most handy and reliable book of its kind available for use at the doctor's desk. "The collection of information in all branches of medicine and surgery must have been a herculean labour, and the book moves us to admiration of the thoroughness and attention to detail shown."

—British Medical Journal

68 tenants RESCUED FROM SMUTS!

Block of London Flats points the way to smokeless, smutless homes for all!

A block of working-class flats: you see it from the train a short way out of Paddington. In their old homes practically all the tenants had open smoky fires in their living rooms. Now every tenant cooks, heats and gets hot water by smokeless fuel—Gas or Coke. You should hear these housewives talk!

GAS and COKE. A miracle, of clean homes, free from drudgery! And a miracle that you can bring to your home, too. A fire that makes smoke is always sending tiny particles of soot and dirt out into the room. Haven't you noticed how your living room covers get dirtier than those in the bedrooms? Don't you say—'We won't spring-clean till we've stopped using fires'? Gas and Coke will halve your housework, keep everything twice as clean twice as long—and coke costs 2d. in the 12 on fuel!

**NO SMUTS—NO SMOKE
WITH
GAS AND COKE**
the fuel of Clean Homes
and Clean Cities

Issued by the BRITISH COMMERCIAL GAS ASSOCIATION, GAS INDUSTRY HOUSE, 1 GROSVENOR PLACE, LONDON, S.W.1

I can help you to make England healthier'

says Mr. Therm

Many prominent medical men have pointed out that a great deal of disease and illness is due to fog and grime from smoking chimneys, and that the solution of this smoke problem is of national importance.

There is only one way to end smoke, and that is to persuade women to give up the old-fashioned, smoking fire which is responsible for 70% of city fog and grime.

In the campaign which it is conducting to convert women to the use of gas and coke—the fires without smoke—the British Commercial Gas Association is in a happy position of knowing that it is not only promoting its own interests but is also contributing to the improvement of the public health. Mr. Therm is greatly encouraged by the knowledge that his efforts to clean up the air over England's cities have the approval of the Medical Profession.

"Spare the petrol and spoil the performance" is no gain—

New Wolseley cars give both increased m.p.g. and livelier acceleration.

HOW? Wolseley engineers have developed a new cylinder head technique as a result of research into modern petroleum technology. This provides flashing acceleration and speed when you want them or strict economy for unhurried cruising. You get more power as well as more mileage per pint of petrol. And with added power comes the ability to use it to full advantage

on the road, thanks to the phenomenal road-holding qualities of the new cars.

And speed in a Wolseley car means speed in comfort and without strain. Accommodation is increased, every feature that makes for ease of handling is incorporated. In their respective classes the new Wolseley cars represent the greatest value it is possible to obtain today.

THE IMPORTANCE OF PRECISION POLISHING

In order to obtain uniformity of calibre and complete roundness of strand along its entire length, A. & H. Catgut is polished by automatic machinery.

Hand polishing of individual strands fails to obtain this desirable precision and uniformity in the production of surgical catgut strands.

One of the modern advantages incorporated in the production of A. & H. Catgut.

The entire product
manufactured
in England.

*A descriptive booklet will
be sent on application.*

Precision Automatic Polishing, in one operation, of twelve catgut strands, each 10 feet in length.

'... in a variety of inflammatory conditions' — M.B.Ch.B.

A mass of evidence has accumulated since the introduction of S.U.P. 36 over twelve years ago testifying to its value in a wide range of inflammatory conditions. This range is indicated in a letter received recently from a physician, in which he states :—

'I have used S.U.P.36... with great success in a variety of conditions ranging from acute pleurisy to septicæmia, and some other types of inflammation such as ascending phlebitis and acute fibrositis of the shoulder muscles...'

Any physician wishing to make a trial with S.U.P.36 is invited to write in for a sample and descriptive literature.

Colitis - Scourge of Civilisation

—Chronic

(Simple Mucous, Muco-Membraneous, Post-Dysenteric.)

Alternating intervals of constipation and diarrhoea often occur in cases of colitis. Kaylene-ol is applicable in either phase. Its soothing and adsorptive actions combat the irritative diarrhoea, and its softening and lubricating actions counteract constipation during the intervals.

DOSE—KAYLENE-OL: 1 or 2 dessertspoonsful three times a day, half hour before meals, or in mild cases half hour before breakfast and at bedtime.

Kaylene-ol 2 Phenolphthalein (0.5 per cent.) is taken when constipation is particularly troublesome. Dosage as for Kaylene-ol.

To prevent complications in Gonorrhoea

ARGYROL

BRAND SILVER VITELLIN

"STRONG ANTISEPTICS not only fail to control the infection but actually increase the inflammation and stimulate bacterial activity by virtue of the tissue trauma which is thus introduced."

* So writes a noted urologist in discussing the prevention of complications in gonorrhoea.

Frankly, Argyrol is not a *strong* antiseptic in the test-tube; in the infected urethra, however, because of its unique mildness and sedative effect, Argyrol not only destroys the surface gonococci but stimulates healthy tissue reaction and hastens normal restitution. Which means a cure without complications. Thirty-six years of satisfactory service in the treatment of gonorrhoea has made Argyrol the standard therapy throughout the world.

It should be emphasized that Argyrol is not just another "mild silver protein." It is different because its constituent elements are different.

Argyrol is in a class by itself—*sui generis*. It has never been duplicated and it is the only silver salt which does not become irritating with increased concentrations.

Insistence on having the name ARGYROL on all solutions ordered or prescribed, will ensure the clinical results you expect.

* Urol. and Cutan. Review, Vol. XXXIX, Nov. 9, 1935.

'A.B.' PROTAMINE INSULIN

(with zinc) SUSPENSION

Effect of Insulin without and with Protamine

The absorption of insulin injected in the form of 'A.B.' Brand Protamine Insulin (with Zinc) Suspension is much prolonged and closely resembles the natural secretion of the pancreatic islets. This insulin has a steady action and exerts a better control than that of ordinary insulin over the carbohydrate metabolism. The number of injections can be reduced, a lower total dosage is usually necessary, and the subjective symptoms of diabetes markedly improve.

40 units per c.cm.
5 c.cm. (200 units) 2/4
10 c.cm. (400 units) 4/6

80 units per c.cm.
5 c.cm. (400 units) 4/6

INSULIN 'A.B.' was the first British insulin offered commercially to the medical profession, and has a world-wide reputation for its strictly safeguarded sterility, its carefully standardised strength, its freedom from toxic reactions and its stability in hot climates.

Nestlé's **HOMOGENISED** Fruits & Vegetables

simplify infant feeding

THE problem of how vegetables and fruits could be added to the milk diet without any disturbance to digestion has been solved by the homogenisation of these foods. This process breaks down the cell walls and reduces the foods to such fine particles that they are as easily digested as milk. Nestlé's now supply Homogenised Fruits, Vegetables

and Soup in correctly balanced combinations. Thus guesswork for the mother is eliminated, and the medical adviser can be sure that his instructions for adding fruits and vegetables to the milk diet are carried out to the letter. A booklet on the subject and a description of the foods, together with ample supplies for your own investigation are now available, and will gladly be sent on receipt of the coupon below.

The nicest way of taking the natural vitamins A, C & D

HALIBORANGE presents Allenburys tasteless and odourless Halibut-Liver Oil, associated with additional vitamin D and concentrated Orange Juice.

One teaspoonful of HALIBORANGE is equivalent in vitamins A and D to one teaspoonful of cod-liver oil, and in vitamin C to two teaspoonfuls of fresh orange juice.

HALIBORANGE is an excellent addition to the diet of babies as a precaution against rickets and scurvy. For older children, adolescents, or adults, it is a prophylactic vitamin tonic.

PROPHYLAXIS OF COMMON

WINTER RESPIRATORY

INFECTIONS

Antiseptic gargles and sprays have an important place in the prevention of colds, tonsillitis and other winter ailments. But, for optimum efficiency, the antiseptic used must have certain "plus" features, in addition to high bactericidal properties. T.C.P. is an ideal antiseptic for this purpose, because it has so many of these "plus" characteristics. Chief among them are *stability*—the maintenance of germicidal efficiency in the presence of organic matter, saliva, blood, pus, etc.; *safety*—T.C.P. is neither irritant nor caustic; *penetrative power*—for the relief of congestion and the stimulation of capillary circulation and phagocytosis; and *analgesic action*—invaluable in painful throat conditions.

In Pregnancy and Lactation

THE importance of regular and adequate bowel action is impressed on the patient during antenatal supervision. The question of how to ensure this can be confidently answered by prescribing "Cristolax"—the ideal combination of pure medicinal paraffin with "Wander" Dry Malt Extract.

"Cristolax" is the laxative of choice during gestation, its regular use assisting digestion and ensuring adequate bowel clearance without straining or other unpleasant effects. A noteworthy feature is its pleasant, non-oily taste which does not upset the unstable maternal digestion.

The use of "Cristolax" can be prolonged with advantage throughout lactation. Its gentle but efficient action ensures elimination of toxic material. Unlike many cathartic drugs, "Cristolax" cannot adversely affect the milk, since its laxative component is not absorbed.

LIVOGEN

The Reconstructive Tonic

In addition to liquid extract of liver Livogen contains all the essential members of the Vitamin B complex, including Vitamin B₁, lactoflavine and nicotinic acid which are concerned in the physiological activity of the brain and nervous system. Deficiencies of these substances, although usually not marked, are common. Livogen, therefore, is a valuable tonic in debilitated conditions particularly when symptoms of neuritis, neuralgia and other nervous dysfunctions are present.

| Sodium Benzoate | 1.00 |
| Effervescent Base | ad 100 |

DIRECTIONS

One teaspoonful to be taken morning and night in a tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which assists general metabolism, and after it has played its part is eliminated together with the normal thyminic acid of the organism. When, however, uric acid is present in excess, the body needs additional thyminic acid to supplement the resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid, which, being in excess of normal, necessitates treatment by an agent capable of enhancing elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin, stimulates the organism to eliminate the pathological uric acid already dissolved by its thyminic acid content.

A PRODUCT OF
THE EVANS BIOLOGICAL INSTITUTE

OVALTINE

FOR THE OLD AND FEEBLE

DURING old age, when the digestive powers and vitality are on the wane, the problem of satisfactory feeding often becomes acute. A solution to this difficulty is found in "Ovaltine." Its delightful flavour appeals to the jaded palate, its digestive action aids the enfeebled assimilation, while its high nutritive value stimulates the flagging metabolism. It is a boon to the aged.

In "Ovaltine" the nutritive constituents of fresh milk, eggs and malt are transformed into crisp granules which dissolve readily in milk to form a delicious beverage. A cup of "Ovaltine" in the morning ensures energy for the day and a cup on retiring generally relieves the sleeplessness so common a symptom of old age, and gives digestive rest.

"Ovaltine" enriches the diet in certain important factors, notably calcium and vitamins A and B₂ which recent investigations have shown to promote longevity.

A liberal supply for clinical trial sent free on request.

Laboratories and Works: KING'S LANGLEY, HERTS.

VOLPAR

In a letter to *The Lancet* dated October 22nd, the medical members of the Birth Control Investigation Committee stated that contraceptive methods which involved the use of mechanical appliances are not easily practicable by all elements in the community. 'The possibilities', they add, 'of a chemical method which dispensed with mechanical appliances therefore called for careful investigation'.

In these words were described the origin and objects of an inquiry that has been carried out for ten years under the Committee's auspices. Volpar is the outcome—a contraceptive which, in the Committee's words, is 'spermicidally efficient to a high degree, completely harmless, æsthetically acceptable, and cheap'. Whether Volpar, when used alone, will give complete protection against pregnancy can only be discovered by prolonged clinical trials. These have been begun and, until now, have yielded promising results. The response of Volpar to laboratory tests is superior to that of any other spermicide on the market.

A booklet containing particulars of the investigation which led to the production of Volpar will be sent post free to any physician on request.

Volpar preparations are available in the form of gels and of paste.

Volpar Gels are soluble vaginal suppositories primarily intended for use alone, or (for maximum safety) with a cap or sheath. They are issued in screw-capped glass tubes containing 1 dozen gels: price 2s. 0d. per tube.

Volpar Paste is a non-greasy paste for the lubrication of occlusive caps and sheaths or condoms. It is supplied in collapsible tubes: price 2s. 0d. per tube.

Volpar Gels and Volpar Paste are sold to the public only through the retail pharmacist.

THE BRITISH DRUG HOUSES LTD. LONDON M1

X-ray reveals uniform density of Agarol.

... Agarol has had a physical examination

THE x-ray says: "Look for uniform density throughout as evidence of soundness". Agarol brand Compound is a thoroughly uniform emulsion that acts the same way with every dose.

The microscope says: "Look for the small uniform oil globules" as a sign of thorough emulsification of Agarol. It means stability, freedom from oiliness, ready miscibility with water, milk, fruit juices or any other liquid.

The microscope shows extremely fine division of oil in Agarol.

The pharmacist says: "If it pours freely, it is the sign of a good emulsion." Agarol is a good mineral oil emulsion that has thoroughly proved its value in the relief of acute constipation and in the treatment of habitual constipation.

Descriptive literature and a liberal supply of Agarol supplied gratis to Members of the Medical Profession on request.

Agarol is not advertised to the public

Agarol brand Compound is available 4½, 7½ and 17 ounce bottles.

The average adult dose is one tablespoonful.

WILLIAM R. WARNER & Co., Ltd., Power Road, Chiswick, London, W.4

CRUNCHY FOODS

and mastication

It is generally accepted that improperly masticated food presents difficulties to the digestive system. Mastication stimulates the flow of saliva in the mouth, and renders the food more acceptable to the stomach. Many practitioners believe that this salivation makes the entire work of the digestive tract easier to perform, and therefore that hard foods, because they compel mastication,

have an appreciable value to the digestion as a whole.

Hard foods are now frequently prescribed as a desirable part of the regular diet. Ryvita, a daily bread that is crisp and dry, is recognised to be a valuable addition to the normal diet of to-day.

A complimentary carton of Ryvita will gladly be supplied on request.

The PARKE-DAVIS LABORATORIES

HOUNSLOW, MIDDLESEX

THE English Laboratories of Parke, Davis & Co. are situated at Hounslow, 12 miles west of London. They were established in April, 1900, and the first extension was made in 1907, in which year a building of three storeys was erected. Five years later the growing requirements of the firm necessitated a further addition of more than double the area of the old building. From time to time since, new buildings have been erected, and in 1937 the structure occupying the left half of the above illustration was opened. The total floor space is now nearly a quarter of a million square feet.

In these laboratories extraordinary precautions are taken, regardless of expense, to secure an unequalled standard of activity and reliability in the pharmaceuticals produced. Every ingredient of every formula is critically examined, chemically or physiologically, and required to conform to exceptionally high standards of purity. Elaborate and costly measures are in force to prevent any possibility of error in manufacture, and every product has to pass the rigorous tests of the Analytical Department before it is issued. In every way possible the endeavour is made to ensure that the name "Parke-Davis" on a label shall be a symbol of a product entitled to the implicit confidence of the medical profession.

DOUBLY EFFECTIVE ★ ★ ★

Relieves Nasal Congestion — Combats Infection

Metaphedrin Inhalant No. 99 (Abbott) contains the powerful antiseptic Metaphen, 1 part in 2,500, and Ephedrine alkaloid, 0.95%, in a light, bland mineral oil. • Metaphen has been found to be 250 to 1,500 times more germicidal than phenol, depending upon the organism tested. In 1:2,500 dilution it is non-toxic, non-irritating to mucous surfaces and does not coagulate serum or tissue albumins. The chief value of Ephedrine lies in its power to decongest and shrink the nasal mucous membrane. This is accomplished with little or no irritation.

• This combination of antiseptic and

shrinking actions makes Metaphedrin Inhalant No. 99 an especially useful agent for the treatment of hypertrophic rhinitis, coryza, nasal and sinus infections, and the nasal congestion of hay fever. The product is of great value as a preventive of infection and is frequently used at the onset of certain cases to cut short the course of the disease itself. It is also valuable for instillation into infected sinuses and for use in all rhinological operative procedures. • Metaphedrin Inhalant No. 99 may be applied

topically or it may be prescribed as a spray. It is obtainable through pharmacies and is issued in ½-ounce, 1-ounce, 4-ounce and 16-ounce bottles. Enquiries for a free trial sample of Metaphedrin Inhalant No. 99 (Abbott) and for professional literature are welcomed. The coupon below is for your convenience.

A Solution to a HEALTH PROBLEM

"Sunshine and blue skies; farms and homesteads nestling among mountains and hills; blossoms of peach and plum filling the valleys with colour; the perfume of orange groves; the profusion of wild flowers; the camp fire and the thrill of wild game in the Low Veld; the picturesque kraals and laughter-loving natives; the quest of open roads trailing to far horizons; the sparkling air of the High Veld; sea and sun bathing on golden beaches; the bright warm days and cool starlit nights—these memories and the joyous feeling of health and fitness after my last holiday in South Africa will lure me back there before long."

These are a recent visitor's impressions of a South African holiday.

Those concerned with problems of health might well consider the benefits to be derived from exchanging the rigours of a European Winter for "Sunshine and blue skies." It is now only a fortnight's voyage to

SOUTH AFRICA

Illustrated brochures, including one entitled "Medicinal Springs of South Africa," are obtainable from the Travel Bureau, South Africa House, London, W.C.2.

Comfort and enjoyment

are the distinguishing features of a voyage by Ellerman & Bucknall Line. At moderate cost you travel by steamers designed with that knowledge of tropical conditions which is the fruit of long experience.

Spacious public rooms are an epitome of good taste, and extensive decks offer every facility for recreation. Staterooms are commodious and well furnished, and all have windows or portholes. Your freedom is unrestricted as the steamers provide first-class accommodation only.

The cuisine is faultless, the service efficient and the personal co-operation of an expert staff will make your voyage a really ENJOYABLE INTERLUDE.

ASPECTS OF THE HISTORY OF ANAESTHETICS*

BY

A. J. CLARK, M.D., F.R.C.P., F.R.S.

Professor of Pharmacology, University of Edinburgh

I feel that since I am neither a medical historian nor an anaesthetist I owe an explanation to this Section for my choice of subject. The history of the discovery of anaesthesia has been worked over with meticulous care, partly because of the dramatic suddenness with which it occurred, and partly because of the unhappy controversies which marred much of the history of this remarkable advance in human knowledge. The subject, therefore, is not merely well-trodden ground, but, as regards the pitfalls and entanglements with which it abounds, is as uninviting as some abandoned battle area. None the less I venture upon this dangerous field because the whole subject has great interest for the pharmacologist.

Pharmacology is one of the youngest of the medical sciences; it is, indeed, a growth chiefly of the twentieth century, and in consequence has very little history. Only three discoveries of major importance to pharmacology were made in the nineteenth century—namely, anaesthetics, antiseptics, and endocrine therapy—and of these only the first is favourable for historical survey.

Endocrine therapy was initiated by the discovery of the action of thyroid, which constituted the beginning of a new branch of science, but this subject is still developing at great speed; it obviously is not yet approaching maturity, and hence is at present unsuited for historical treatment. Antiseptics suddenly assumed a dominant importance in surgery, but the development of aseptic technique caused their importance to decline as rapidly as it had grown and their history is too irregular to be of general interest.

The discovery of anaesthetics is the only pharmacological advance of major importance made in the nineteenth century that has reached mature development and therefore can suitably be treated from the historical aspect.

The importance of this discovery for the history of pharmacology is further increased by the fact that this was the first occasion on which the synthetic products of the organic chemist were used to produce a therapeutic effect of major importance. Since then the use of such compounds has developed steadily, and to-day they form the chief basis of therapeutics. Modern pharmacology may therefore be said to have begun with the introduction of anaesthetics, and indeed the only later events of comparable importance in the history of the science are the introduction of thyroid therapy and the discovery of

salvarsan, which respectively initiated the sciences of endocrinology and of chemotherapy.

These are adequate reasons for a pharmacologist taking a special interest in the history of anaesthesia, and a general survey reveals outstanding facts that are of great importance in relation to the problem of how a profession reacts to the impact of new ideas and a new technique. It is, moreover, of interest to study the course of discovery and to note the points at which progress was rapid and those at which halts occurred, since such a study gives hints regarding the factors which influence the advance of scientific knowledge.

Sudden Discovery of Surgical Anaesthesia

A casual survey of the discovery of anaesthesia suggests that it took place with almost explosive rapidity. In 1844 Wells produced surgical anaesthesia with nitrous oxide, in 1846 Morton did the same with ether, and in 1847 Simpson introduced chloroform. In September, 1846, the possibility of surgical anaesthesia was not generally recognized; by the end of November, 1847, chloroform and ether were in widespread use, and both nitrous oxide and ethyl chloride were known to be possible anaesthetics. In 1846 the only mention of anaesthesia in the *Lancet* was a short note on the new use of ether in the last number, while less than four months later (April 10, 1847) the editor referred to ether as "a remedy which has already produced such an unparalleled influence on the practice of surgery in this country," and mentioned that the number of operations had doubled. Throughout 1847 the *Lancet* maintained a special column describing "operations without pain."

The essentials of modern anaesthetic practice were therefore mastered almost within a year. Many advances have been made since then, but it will be generally agreed that ether, nitrous oxide, and chloroform are together more important than all other known agents. An anaesthetist could manage better if confined to the three agents mentioned than he could if deprived of these three and allowed his choice of all others.

This period of remarkable advance was followed by a long period of quiescence, and it is only during the last fifteen years that a really active search for new agents has begun again.

More detailed examination of the development of knowledge shows that it was not quite so abrupt as suggested above, but none the less the suddenness of the initial advance is the outstanding feature in the history of anaesthesia, and the factors that caused this phenomenon are of obvious interest.

* Presidential address to the Section of Pharmacology, Therapeutics, and Anaesthetics at the Annual Meeting of the British Medical Association, Plymouth, 1938.

Factors Leading to the Discovery

The advance was essentially the mastery of a successful technique. There are two easily recognizable types of advance in knowledge. In one case something new is discovered the existence of which had previously been unsuspected; for example, the discoveries of x rays and of radium. The other case is when the aim is obvious but the means of attainment are lacking, and the advance consists in finding the right technique. The discovery of anaesthesia was of this latter kind, for the alleviation of the pain of operations was an obvious aim indicated by ordinary motives of humanity, and since classical times medicine had been acquainted with the stupefying power of many drugs. Sir J. Y. Simpson (1871) pointed out that there was evidence of the regular use of stupefying agents such as opium and mandragora in both classical and mediaeval surgery. Curiously enough, this knowledge appears to have been lost at about the Renaissance period.

The essential importance of establishing an efficient technique will, I think, explain the history of the oldest of the anaesthetics—namely, nitrous oxide—though at first sight this history is very surprising.

Nitrous Oxide

The discovery of the pharmacological actions of nitrous oxide is of special local interest, since it is closely associated with the West of England. Sir Humphry Davy, who was born and bred near Penzance, began studying for medicine by being apprenticed to a surgeon apothecary in Penzance, but in 1798, when 20 years old, he went to work under Dr. Thomas Beddoes at the Medical Pneumatic Institution in Bristol. After two years of work (1800) he published his *Researches, Chemical and Philosophical, chiefly concerning Nitrous Oxide*. This volume is a model of a pharmacological research complete in all its stages. It starts with a masterly investigation of the chemical properties of nitrous oxide, proceeds through a series of well-planned pharmacological researches upon a wide variety of animals, continues with an investigation into the actions of the gas on man, and concludes with a brilliant deduction regarding its therapeutic value. On the last point Davy's actual words were (p. 556):

"As nitrous oxide in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations in which no great effusion of blood takes place."

The only criticism to be made of these experiments is that Davy took somewhat extreme risks with his own life since he repeatedly inhaled nitrous oxide to the point of unconsciousness and proved that the gas "could be respired without danger by a human animal for a much longer time than that required for the death of smaller quadrupeds in it." Among his many discoveries was the demonstration that pure nitrous oxide produced death in animals, but that unconsciousness, with subsequent revival, could be produced by nitrous oxide mixed with a little oxygen or ordinary air.

Davy's brilliant researches bore no immediate fruit. Hickman (Wellcome Museum, 1930), a country practitioner in Shropshire, made a series of attempts in 1824 to produce surgical anaesthesia by inhalation of gases. He published a pamphlet showing that dogs could be rendered unconscious with carbon dioxide, could be operated on in this condition, and afterwards recovered. In a memorial to Charles X (1828) he stated that anaesthesia could be produced by certain gases. The memorial was referred to a commission of the Académie Royale de Médecine, but the only member interested was the famous Baron Larrey. Nineteen years later the rapporteur of this commission (Gérardin) stated that nitrous oxide was one of the gases mentioned by Hickman. The latter died in 1829, aged 29, having received no encouragement either in England or in France. He certainly demon-

strated the possibility of producing surgical anaesthesia by the inhalation of carbon dioxide, but the extent to which he investigated nitrous oxide is doubtful.

Neglect of Davy's Work on N_2O

The use made of Davy's brilliant researches does not increase one's respect for human intelligence, since the suggestion about anaesthesia was almost completely ignored for forty years, while the fact that nitrous oxide produced a ludicrous form of intoxication was eagerly seized upon and exploited. Progress, however, occurs through unexpected and unpromising paths, and these silly demonstrations proved of ultimate value. Horace Wells, the surgeon dentist of Hartford, Connecticut, saw one of these displays of laughing-gas, and on December 11, 1844, arranged for the gas to be used upon himself, and achieved the painless extraction of a tooth under anaesthesia. Apparently he had never heard of Davy's suggestion. Wells tried to demonstrate the use of gas at Massachusetts General Hospital, but the demonstration was a failure, and the sensation attending the discovery of ether anaesthesia two years later caused nitrous oxide to be neglected and forgotten. In 1863 Colton in New York popularized the use of pure nitrous oxide in dental operations, and in 1868 Edmund Andrews of Chicago showed the advantages of using nitrous oxide with 10 per cent. of oxygen—a method that Davy had investigated on animals nearly seventy years previously. Nitrous oxide was established in general use in Great Britain about 1870.

In view of the present importance of nitrous oxide this history is very extraordinary. It would appear that Davy established the possibility of anaesthesia with gas and oxygen, that this invaluable discovery was completely neglected for forty years and its true value not established for seventy years, while in the intervening period the gas maintained a steady popularity in virtue of its power to produce a ridiculous intoxication.

Before judging such apparent stupidity too harshly it is well, however, to consider the probable limitations imposed by imperfections of technique. The genius of Davy was unique, and although he could produce nitrous oxide pure enough to permit him to inhale it repeatedly to the verge of unconsciousness, yet it is probable that few others had a similar skill. For example, in 1847 Orfila gave the following account of his experiments with nitrous oxide (Hickman, 1930):

"J'ai répété leurs [Davy et al.] expériences, et j'en ai éprouvé de si vive douleur dans la poitrine et une telle suffocation, que je suis resté convaincu que si j'eusse continué l'expérience, je n'en serais pas revenu."

Nunneley in 1849 came to a similar negative conclusion, for he experimented on some 300 cats with a wide range of possible anaesthetics, and concluded that his experiments were "quite sufficient to show that nitrous oxide never could be employed as an anaesthetic and that the inhalation of it is not altogether so harmless as is generally stated."

It must have been very difficult indeed to produce a satisfactory nitrous oxide anaesthesia when the gas available was of doubtful purity and the most portable form of container was a balloon. There are therefore circumstances palliating the failure of the medical profession to utilize the gift which Davy offered them, but, even so, one cannot claim that the history of nitrous oxide redounds to the credit of anyone except Davy and Wells. Indeed, an enemy of our profession might claim that it showed extreme slowness and conservatism in accepting the gift offered by science.

Ether Anaesthesia

The history of ether contrasts sharply with that of nitrous oxide. Ether was one of the earliest known of the synthetic organic drugs, and its synthesis was

described by Valerius Cordus in 1546. In 1794 Dr. R. Pearson used it in the treatment of phthisis (Gardner, 1847) and suggested its investigation to Beddoes. After a few trials at the Pneumatic Institute it was found to be serviceable as an anodyne. Apparently its intoxicating powers soon became fairly common knowledge. Dr. Graham, of "celestial bed" fame, was accustomed about 1802 to inhale ether several times a day (Lee, 1847). In 1818 a note believed to have been written by Michael Faraday was published which pointed out that ether had intoxicant effects similar to those of nitrous oxide.

The medical profession was therefore fairly well acquainted with the intoxicant action of ether, and many persons probably knew that excess of ether might lead to unconsciousness. In 1844 Jackson and Morton witnessed Wells's abortive demonstration with nitrous oxide, and in 1846 Morton used ether for the painless extraction of teeth. On October 16 he administered ether for a surgical operation in Massachusetts General Hospital. Morton was more fortunate than Wells; his public demonstration was a complete success, and the speed with which its fame spread round the world is truly remarkable.

On December 19, 1846, a tooth was extracted under ether in London, and two days later the drug was used for two operations performed by Liston at University College Hospital; within a few days the fame of ether had spread to Edinburgh and to Paris. Sir J. Y. Simpson (1847a) immediately (January 19, 1847) used ether to relieve the pain of childbirth, and within three months it had revolutionized surgical practice in Great Britain.

Reception of the Discovery

The manner of the reception of the news of the discovery of anaesthesia in Great Britain is thus described by a contemporary (Miller, 1848):

"It fell on no dull or idle ears. It was taken up, tried, and speedily re-echoed; and in a few days it filled the island. The profession were surprised, excited, charmed in the mass; and more especially those on the sunny side of the grand climacteric. The elderly gentlemen had their preconceived and heretofore settled notions sadly jolted and disturbed; not a few grew irritable, and resented the interference, but the thing was too fast, the first impulse too strong, and the promoters too numerous and nimble to be so obstructed."

In the case of nitrous oxide it was necessary to explain and palliate the inertia of our profession, but the history of the reception of the discovery of ether is wholly creditable, for its use appears to have sped round the world as fast as the posts could carry the news.

The contrast between the fate of the two drugs suggests a kind of all-or-none effect where a discovery depends on the attainment of an adequate technique. In such a case if the results are immediately convincing and obvious, and the introduction is attended with reasonable good fortune, the discovery attains a momentum that sweeps away opposition. If, on the other hand, there are hitches owing to imperfect technique or mere bad luck, then a discovery of comparable importance may peter out and be forgotten for a generation.

The introduction of ether as an anaesthetic was attended by many unfortunate circumstances on which it is unnecessary to dwell. There was a quarrel between Jackson and Morton, an attempt at secrecy and a patent. All who are condemned to survey modern medical literature will sympathize with the bad luck of Crawford W. Long, a rural practitioner in Georgia who in 1842 used ether to produce anaesthesia in several operations. He had been so impressed by the injunctions of his professors not to swell medical literature by premature publication of incompletely verified work that he did not publish his results until 1853. Hence the most laudable of motives caused him to miss much well-deserved fame.

Incidentally the attempt to take out a patent was eagerly seized upon as a pretext for opposition to a new idea. The following was the reaction of the *Philadelphia Medical Examiner* to anaesthesia in December, 1846 (Hoff, 1937): "We are persuaded that the surgeons of Philadelphia will not be seduced from the high professional path of duty into the quagmire of quackery by this will-o'-the-wisp." After a passing reference to the ethics of using a patent medicine and a lament for the decadence of Boston, the editor concluded that "physicians and quacks will soon form one fraternity."

The credit for the discovery of ether was a subject of prolonged inquiry and controversy, but the matter was well summed up by Jacob Bigelow in 1870 in a letter to Simpson (1871): "As far as we know, he [Morton] is the only man, without whom anaesthetic inhalation might have remained unknown to the present day." I feel that this is the final criterion in apportioning credit for an advance. Discoveries are scarcely ever the sole work of one person. All research workers stand on the shoulders of their predecessors, and if current knowledge is adequate to suggest a possible advance to one person, it is nearly certain that the same idea will have occurred to many others. There is, however, a world of difference between a bright idea and a successful achievement, and the main credit must always go to the man who possessed the energy and determination and skill to demonstrate the possibility of progress along some new path.

Chloroform

The discovery of chloroform was the third outstanding event in the discovery of anaesthesia. The trial of chloroform by J. Y. Simpson and his friends, and its successful use as an anaesthetic for major operations at the Royal Infirmary of Edinburgh on November 15, 1847, are celebrated historical events. The first operation was performed by Professor Miller, and was witnessed by Dumas the chemist and by Christison. There has been debate on the extent to which Simpson was helped or even anticipated by others, and since this is a matter of special interest to Edinburgh, I feel justified in digressing briefly to discuss this point.

Christison (1886) in 1868 wrote the following account of his colleague's achievement:

"In 1832 Soubeiran in Paris and Liebig in Germany simultaneously discovered chloroform. In 1835 Dumas ascertained its leading physical and chemical properties and its correct elementary constitution. In 1838 Dr. Forby of Liverpool first used it as a medicine inwardly as a soothing antispasmodic. In 1842 Dr. Mortimer Glover, a young Edinburgh graduate, discovered by experiment that it is a powerful narcotic poison, and that one of its effects as such is to produce insensibility."

Gilmour (1908) states that Dr. Black of Bolton used chloroform as a medicine in 1833. It is said that Glover tried chloroform on human subjects (Davidson, 1908). Furnell, working under John Bell and Co., London, is said to have experimented on himself in the summer of 1847. Christison states that in March, 1847, the French physiologist Flourens proved that the inhalation of chloroform causes in animals precisely the temporary anaesthesia caused by the inhalation of ether.

Events Leading to its Use

Christison also made the following statement in 1870:

"On asking Dr. Matthews Duncan to repeat a remarkable statement he made to me a few months ago, relative to his concern with the discovery of the anaesthetic virtues of chloroform, he gave it to me thus. One day when Sir James Simpson and he were in Dr. Gregory's laboratory at the College, he (Dr. Duncan) got possession of every liquid in the laboratory which he imagined 'would breathe.' Four or five bottles were thus carried off, and chloroform was one. At this time the correspondence with Mr. Waldie about anaesthesia and the suggestion by that gentleman to try chloroform had not been heard of by Dr. Duncan. One forenoon Dr. Duncan made trial of the chloroform. He had previously

experimented on himself with various substances, but found none suitable. On trying chloroform, he was convinced that the article sought for was found. The same or next evening the trial was repeated by Dr. Keith, Sir James, and himself. This was the trial which is now a matter of history; but the previous trial has never been noticed.*

Dr. Duncan was at that time assistant to Sir James Simpson in his scientific work, and undertook this special inquiry under his general guidance. With regard to the earlier trials noted above, it may be mentioned that the only commercial form in which chloroform was available was a weak alcoholic solution termed "chloric ether," and this was used in most cases.

The David Waldie mentioned above, who was chemist to the Apothecaries' Company in Liverpool, devised a method of separating pure chloroform from chloric ether. On November 29, 1847, he gave the following account at Liverpool of the manner in which he suggested the use of chloroform to Simpson:

"The vapour of the so-called chloric ether seems to have been tried as a substitute for sulphuric ether in February or March last,* but without very satisfactory results, which indeed could scarcely be expected, unless the vapour of alcohol possessed the same properties, it being composed principally of alcohol. When in Scotland, in October last, Dr. Simpson introduced the subject to me, inquiring if I knew of anything likely to answer. Chloric ether was mentioned during the conversation, and being well acquainted with its composition and with the volatility, agreeable flavour, and medicinal properties of chloroform, I recommended him to try it, promising to prepare some after my return to Liverpool, and send it to him. Other engagements and various impediments† prevented me from doing this so soon as I should have wished, and in the meantime Dr. Simpson, having procured some in Edinburgh, obtained the results which he communicated to the Medico-Chirurgical Society of Edinburgh on the 10th of November, and which he published in a pamphlet entitled: 'Notice of a New Anaesthetic Agent as a Substitute for Sulphuric Ether in Surgery and Midwifery.'"

Simpson wrote in a footnote to the pamphlet mentioned that Mr. Waldie had named chloroform to him as worthy among others of a trial. Waldie emphasized the fact that he had played only a small part in the discovery of the anaesthetic properties of chloroform, but thought that Simpson might have been more generous in his recognition of this help, since he had recommended the trial of pure chloroform, which at that date was not known as a commercial article.

These accounts suggest that Simpson was, as Waldie complained, somewhat economical in his recognition of the help he received both from Waldie and from Matthews Duncan. Nevertheless the popular tradition that associates Simpson's name alone with the introduction of chloroform would appear to be substantially correct. The discovery of surgical anaesthesia was not a revolution in ideas, but the attainment of a goal which others had striven for without success. After the establishment of ether many persons up and down the country were trying out all likely volatile fluids. The essential advance was not the idea of trying chloroform but the provision of proof that not only did it produce anaesthesia but that in some respects it appeared to be superior to ether.

Simpson also seems to have the honour of being the first to use anaesthesia in labour, but this advance was almost inevitable after the discovery of anaesthesia, and the question who was first is not important. It is indeed probable that the witch-cult were the real pioneers in the production of "painless labour." They appear to have retained the knowledge of the use of narcotics to produce coma which was common in mediaeval times and lost at a later date. The descriptions of the composition and the use of their "flying ointment" establish this point fairly clearly. They appear also to have used such drugs to relieve the pains of childbirth. Unfortunately the accounts of the witch trials are such a medley of

fact and fiction that one cannot draw from them any certain conclusions. For example, Agnes Sampson of North Berwick was accused of having taken away the "natural and kindly pains of labour" from Euphemia MacCalyan of Edinburgh, and this suggests the use of narcotics; but the account proceeds to state that the pains were cast upon "the wanton cat of the house," which vanished. At the time of the trial the evidence was deemed completely convincing, and both women were burnt alive in 1591, but to-day it is obviously difficult to decide how much, if any, of the tale was true.

Chloroform attained immediate popularity, but it is of interest to note that it narrowly escaped an initial disaster, which might have prevented its employment for decades.

Immediate Success of Chloroform

Chloroform was first used for an operation at the Royal Infirmary, Edinburgh, on November 15, 1847. A test had been arranged two days previously, but Simpson could not attend, and therefore chloroform was not given on this occasion. The operation was for hernia, and the patient died when the first incision was made through the skin (Simpson, 1852). It is very probable that the same tragedy would have occurred if chloroform had been used, when it would certainly have borne the whole blame, and the incident shows how much the initiation of a new therapeutic measure may depend upon good fortune.

Chloroform made such an easy success that at first it seemed that there would be no scope for Simpson's zest and talent for controversy. This, however, was provided for him by the action of certain ministers and medical men who claimed that relief of the pains of childbirth was contrary to the Scriptures. Possibly these ministers hoped to revive some of their old triumphs of the seventeenth century, when the number of midwives they caused to be burnt as witches must have formed a considerable proportion of those practising this profession. Times had changed, however, and it is only fair to the churches in Scotland to record that Dr. Chalmers gave the opinion that if some "small theologians" really took such an improper view they were too foolish to merit serious attention. Simpson, however, plunged with delight into the controversy; he fought his opponents on their own ground—namely, the interpretation of the biblical texts—and scored a fairly easy triumph.

Far longer and more serious was the controversy between Boston and Great Britain over the relative merits of ether and chloroform. This controversy practically ended in 1871, when the *British Medical Journal* threw its great influence on the side of ether.

Investigations of Deaths from Chloroform

Deaths from chloroform soon occurred, and the first case (January 28, 1847) happened to be typical. A girl of 15 had had one great toe successfully removed under ether, and two months later chloroform was given for the removal of the other one. The patient died suddenly within two minutes of the beginning of anaesthesia. The occasional occurrence of sudden and wholly unexpected deaths of this type under chloroform naturally attracted much attention. The history of the investigations made upon this subject in the ensuing sixty years provides chastening reading for laboratory workers, because the early clinical observers at once divined the nature of the phenomenon, while the laboratory workers in later years were persistently at fault.

In 1848 Sibson analysed the first four deaths from chloroform, and concluded: "In all the four cases it is manifest that the immediate cause of the instantaneous death lay in the heart." In February, 1849, it was noted in a case of chloroform death that the blood ceased to flow before the respiration stopped (Nunneley, 1849). Snow (1858) made a masterly analysis of fifty cases of death from chloroform, and showed that in at least forty of these cases death was due to cardiac syncope and not to overaction of chloroform on the brain or medulla.

* Presumably the experiments referred to by Christison.

† 11. Laborants were burnt down.

Deaths under chloroform attracted so much attention that committee after committee was appointed to investigate their cause, but the reports chiefly serve to provide a striking proof of the fact that committees are not an effective mechanism for the solution of scientific problems.

A commission which reported to the Society of Emulation of Paris in 1855 concluded that in all instances in which animals were killed by chloroform the action of the heart survived the respiration (Senn, 1858). The Hyderabad Commissions (1888, 1889) concluded that there was no such thing as chloroform syncope and that the heart was the last organ to give in under the action of chloroform (Lawrie, 1891). The *Lancet* (1889) pointed out, however, that this conclusion was opposed to those arrived at by the previous commissions appointed by the Royal Medical and Chirurgial Society and by the British Medical Association. A later commission set up by the B.M.A. (1903) nevertheless directed all its attention to the question of overdosage of chloroform.

In 1908 the Commission on Anaesthesia of the American Medical Association concluded that "all of the accidents of chloroform are due to overdosage" (Haggard, 1908). These commissions included many distinguished physiologists. Their conclusions were perfectly correct as regards the subject they studied—namely, the effect of gross overdosage of chloroform—but unfortunately this has no relation to death in the early stages of chloroform anaesthesia. It is difficult to believe that any of these commissions could have studied Snow's excellent treatise. In this he describes fully the manner in which overdosage of chloroform kills an animal, and then remarks:

"In examining the recorded cases of fatal inhalation of chloroform, we shall find, however, that they have none of them taken place in this gradual manner; but that in all cases the fatal symptoms, if not the actual death, have come on very suddenly."

This history illustrates clearly an essential limitation of laboratory methods; like most methods of exact analysis, they yield peculiarly ridiculous results unless they are directed to the correct object. The prolonged failure recorded above has since been redeemed, and to-day it is possible to produce cardiac syncope with chloroform as a laboratory demonstration.

Other Anaesthetic Agents

The discovery of ether and chloroform stimulated intensive research into the properties of other gases and volatile liquids. As already mentioned, Flourens in 1847 described the anaesthetic action of ethyl chloride as well as chloroform. In 1848 Nunneley investigated on cats the anaesthetic action of numerous substances, and incidentally described the effects produced by a mixture of ether and an alcoholic solution of chloroform (A.C.E. mixture). Workers such as Nunneley, Snow, and Richardson examined the anaesthetic properties of a wide variety of gases and volatile liquids. Some of these, such as ethylene, afterwards became established. The general rule that "the good is the enemy of the best" came, however, into operation; nothing was found which showed a clear superiority over chloroform or ether, and in consequence research died down. The generation that had witnessed the revolutionary advance continued to work in the hope of discovering something new and better, but when these died out the younger generations who had been trained with chloroform and ether accepted these and their imperfections as established institutions and scarcely thought of the possibility of major advances.

Continual minor improvements in technique were made, but there was extraordinarily little change until about 1923. Since that date new volatile anaesthetics such as ethylene and cyclopropane have been introduced, intravenous anaesthesia with sodium evipan has achieved great popularity, and a wide variety of methods of basal narcosis has been investigated.

With regard to methods of basal narcosis, it is interesting to note that the use of such substances as urethane and paraldehyde for this purpose was established as a routine method in physiological laboratories by the end of the nineteenth century. The long delay in applying these routine laboratory methods to anaesthetic practice is remarkable.

Points on the Progress of Therapeutic Knowledge

This brief summary of the history of anaesthesia reveals some interesting points concerning the progress of therapeutic knowledge. The problem of anaesthesia is the discovery of the optimum technique for producing a certain well-defined effect. This effect is not an end in itself, but is for the purpose of facilitating surgical procedures. The history of the introduction of anaesthetics shows that that advance tended to be an all-or-none process and that the result was largely dependent on good luck. The whole history of anaesthesia might have been different if Wells had chanced upon a good subject and Morton upon a refractory patient for their first demonstrations of nitrous oxide and ether respectively, while in the case of chloroform it is highly probable that its career would have been arrested by a dramatic tragedy if Simpson had not fortunately been forced to postpone his first public trial of the drug.

The speed with which ether and chloroform were adopted is highly creditable to the medical profession. The process was probably assisted by the fact that at that period medical ideas were in a state of flux. The lethal traditions of the "heroic" era were rapidly being discarded; patients with pneumonia were no longer being bled to death, and quinine was replacing calomel in the treatment of malaria.

The history of anaesthesia after 1847 shows clearly one of the major difficulties attending therapeutic advance. The outstanding fact is that thorough familiarity with a technique is equivalent at least to a 30 per cent. difference in efficiency. If a person has mastered a technique it is not worth his while changing to a new and unfamiliar one unless the change promises some big advantage.

It is obvious that after a technique has become fairly effective the likelihood of any major advance is lessened. The history of engineering shows, however, that continuous small advances can add up to constitute a large effect, and there seems no reason why this should not be true in pharmacology.

Need for Further Technical Advance

I think it will be generally agreed that further progress in the technique of anaesthesia is very desirable. The fact that deaths under anaesthesia are increasing rather than decreasing indicates that we are far from having attained perfection. There is a tendency to assume that because the pioneer advances were due to uncoordinated individual enterprise, therefore this remains the best method. I would suggest, however, that although organization is of little service in promoting original thought, yet there comes a stage of development when further progress can only be made by co-ordinated work. This stage has probably been reached in the development of anaesthesia. To decide whether a new anaesthetic constitutes a significant advance is a difficult task, for not only must its usual action be determined, but it is also necessary to know what chance there is of its producing some rare but unpleasant side-action. These facts can only be ascertained by carefully organized large-scale trials of new agents.

The history of anaesthesia, like the history of many other therapeutic problems, shows that this country shines much more in pioneer investigation than in the development of techniques that have already been established. The United States and Great Britain together initiated anaesthesia; I do not propose to attempt to estimate the relative importance of the contributions of

the two countries, but they were of comparable importance, and no other country can claim any substantial share in the credit. The recent advances in anaesthesia are, however, divided between Canada, the United States, and Germany. The change in our country's position is regrettable. I would suggest that what is needed is an organization of the methods of study of anaesthetics that will permit the accurate estimation of the value of new methods, which, even if they do not provide any sensational advance, yet may be a significant improvement on established methods.

H. C. Ling, L. Greene, and S. E. Pai (*Chin. med. J.*, 1938, 54, 177) record two fatal cases of diphtheria gravis bacteriemia. The first, which is only the second example of the condition to be reported in China, occurred in a boy aged 12 who had a severe attack of faucial and nasal diphtheria and died after about ten days' illness. The gravis type of diphtheria bacillus was isolated from the blood. The second case was that of a girl with grave faucial, laryngeal, and bronchial diphtheria, who died after four days' illness. The gravis type of diphtheria bacillus, together with a non-haemolytic streptococcus, was cultivated from the heart blood seven hours after death.

RADIOTHERAPY IN NON-MALIGNANT UTERINE HAEMORRHAGE*

BY

B. WINDEYER, M.B., B.S., F.R.C.S.Ed., D.M.R.E.

Medical Officer in Charge, Meyerstein Institute of Radiotherapy, Middlesex Hospital

Diagnosis

The first point to be considered in cases of abnormal uterine haemorrhage is the question of diagnosis. Only too frequently do we see patients who have complained of irregular or excessive bleeding at or about the menopause for which no attempt has been made to discover the cause. Many patients believe that such irregular bleeding is a normal phenomenon and do not seek medical advice; but in some cases they do so, only to be reassured, and to be told to wait for a month or two, when the bleeding will stop, no vaginal examination or other investigation being made. It is from cases such as these that a large proportion of patients with advanced carcinoma of the cervix eventually come for treatment, after a delay of months and when the prospect of cure is very considerably reduced or it is impossible. It cannot be emphasized too strongly that when such symptoms appear the patient must be examined immediately and thoroughly for the possibility that the symptoms may have causes other than menopausal dysfunction of the ovaries, and especially must a thorough pelvic examination be made, to exclude malignant disease.

Apart from this all-important question of diagnosis I do not propose to deal with the vast subject of malignant disease of the uterus, but to consider those types of non-malignant uterine haemorrhage in which radiotherapy is employed. These cases fall into three categories: (1) bleeding at or near the menopause; (2) bleeding associated with fibroids; (3) bleeding in young subjects.

How Radiotherapy Acts

The manner in which radiotherapy acts in the treatment of these cases has been the subject of considerable discussion. It is generally agreed that when external irradiation by x rays is the method employed the production of amenorrhoea is due to the destructive effect on the more mature follicles of the ovary. Much experimental research has been carried out on this subject, and Regaud and Lacassagne (1927), describing the effects of radiation on normal tissue, give a clear and concise account of the changes that occur. All ovarian follicles can be destroyed if the dose of radiation is large enough; but there is a very great difference in their radiosensitivity, depending on the stage of maturity. Immature ovarian follicles have little radiosensitivity, and escape apparently unscathed even after heavy irradiation. As they develop, their degree of radiosensitivity increases, until finally the mature follicle is very radiosensitive and is destroyed by only a small amount of radiation. In the ovary of a woman at the end of her reproductive life and approaching the menopause the follicles which remain are either mature or approaching maturity, and therefore are highly radiosensitive. In such cases permanent sterilization can be brought about by moderate doses of radiation. With the young subject, however, this is not the case: some follicles are approaching maturity and are therefore radiosensitive; but the majority have not begun to develop, and need much greater doses for their destruction. A frequent

* Read in opening a discussion in the Section of Radiology at the Annual Meeting of the British Medical Association, Plymouth, 1938.

result of radiotherapy in a young patient is temporary sterilization, with the return of more or less regular and normal menstruation after a period varying from a few months to one or two years.

There is less agreement as to the action of radium placed in the uterine cavity, and two views are commonly expressed: (a) that radium acts on the ovaries as in the case of external irradiation by x rays; (b) that amenorrhoea is produced by a fibrosing action on the endometrium and underlying blood vessels. The usual argument in favour of endometrial action is that, by the physical laws governing the distribution of radiation, the intensity received on the ovaries from radium placed in the uterine cavity can be only a small fraction of that received on the endometrium, and that the dose received by the ovaries would not be sufficient to cause sterilization. Forsdike (1922-3), who strongly supported the theory of endometrial action, has produced evidence of destruction of the endometrium with underlying fibrosis but with demonstrable effect on the ovaries. On the other hand, Corscaden (1935) has demonstrated that in the uterus which had received a sterilizing dose of radium a portion only of the endometrium was obviously affected. Clark and Norris (1927) have observed the destruction of ovarian follicles with regeneration of the endometrium. Actually, assuming that in the average case the ovary is 4 cm. from the endometrium and that, including the thickness of the container, the endometrium is 0.5 cm. from the radium, the dose received from 2,400 mg.-hours filtered by 1.5 mm. platinum with an active length of 4 cm. would be between 10,000 and 20,000 *r* on the endometrium and between 500 and 1,000 *r* on the ovary, depending on their position in each individual case. This is a very heavy dose on the endometrium, and undoubtedly will produce some destruction; but the dose on the ovary, comparing it with the x-ray dose given for sterilization, should be sufficient to destroy the follicles.

Again, amenorrhoea produced by intra-uterine radium is almost always accompanied by the menopausal symptoms of hot flushes (86 per cent. in Moore Patterson's (1933) series). A recent article by Corscaden, Kasabach, and Lenz (1938) points out also that examination of blood and urine of women made amenorrhoeic by radium or x rays has shown the characteristics found in the spontaneous menopause—absence of oestrone and increase of prolactin.

I think the weight of evidence is definitely in favour of action on the ovaries being the main factor in the production of amenorrhoea by radium, but that changes in the endometrium are probably contributory. Abnormal position of the ovaries may account for the small percentage of failures.

I. Irregular Haemorrhage at or about the Menopause

Radiotherapy is undoubtedly the treatment of choice in this condition. In the joint discussions held by the Sections of Radiology and of Obstetrics and Gynaecology at the Royal Society of Medicine in 1933 and in January of 1938 there was general agreement on this question. The advantages of radiotherapy over surgery in this condition are that the same result can be obtained by irradiation with less risk and with a much shorter and almost negligible period of convalescence. The treatment can be carried out either by x rays or by the insertion of radium into the uterine cavity. Whatever the method, a preliminary dilatation and curettage is advisable; if radium is inserted the treatment is completed and the patient returns home with scarcely any more delay than from

curettage alone, while for the actual x-ray treatment she need not even be hospitalized.

Mr. Leonard Phillips (1938) collected from twenty authors over 7,000 cases of menopausal menorrhagia and of fibroids treated by irradiation, with a 95 per cent cure rate. He estimated that over half of these were cases of menopausal menorrhagia. The mortality rate given by twelve authors was under 1 per cent for each series and averaged 0.25 per cent. for the whole. The report of the Radiumhemmet in Stockholm (1937) shows 282 cases of this condition, with only one death from intercurrent disease and only two cases which were not cured.

The mortality rate from x rays is negligible, while the few deaths recorded from radium have been almost entirely due to an occasional embolus. Moreover, in the very small number of failures of radiotherapy subsequent surgery is not rendered any more difficult. The only contraindications in patients about or over the age of 40 would seem to be the presence of an associated prolapse or cervical laceration, which could be cured at the same time by surgical intervention, or the presence of a previous pelvic inflammation: but even this latter need not be a contraindication if x rays are employed and the treatment is given slowly and carefully.

An analysis of sixty-one consecutive cases of menopausal menorrhagia which I have treated at the North Middlesex County Hospital gives the following data:

| No. of Cases | Result | Remarks |
|--------------|----------------------|---|
| 57 | Successful | 37 had no further bleeding 13 had one subsequent period 7 had no subsequent periods |
| 1 | Partially successful | Periods for 15 months at regular intervals, but very scanty in amount |
| 1 | Unsuccessful | Hysterectomy 4 months later for a recurrence of bleeding |
| 2 | | Subsequent history untreated |

COMPLICATIONS AND SEQUELAE

The complications arising from treatment were not serious. The most frequent one was a watery discharge, which was present in twelve cases and persisted from one to four months. The discharge is undoubtedly due to the destruction of a portion of the endometrium by the intense irradiation which it must receive if a sufficient effect is to be obtained on the ovaries. The heavy filtration of 1.5 mm. of platinum and a rubber cover is used to minimize this effect as far as possible. With less filtration one might expect a higher proportion of cases with discharge, and this possibly accounts also for the cases of pyometra which have been described in other series.

Cases of ulceration or cicatricial stenosis of the vagina have been reported after radium treatment, but these have undoubtedly been due either to insufficient packing of the vagina, so that the radium has slipped out of the cervix, or to the use of irritating chemicals in the packing. Corscaden and others have reported cases where a loop of small intestine adherent to the uterus has been damaged by intra-uterine radium and old pelvic inflammation has been lighted up by this treatment, but none of these complications occurred in my own series. In the large number which Phillips collected there were several deaths from embolism, and, as I have said previously, the mortality for the whole series was only 0.25 per cent.

THE CHOICE OF RADIUM OR X RAYS

In my own series of cases radium has been used almost exclusively, and the complications have all been due to radium insertion. Such complications have not been

reported after the use of x rays alone, and the production of amenorrhoea has been just as certain. The main arguments which have been advanced in favour of radium are: (1) That it is necessary to make a thorough examination under an anaesthetic, with dilatation and curettage in cases of menopausal haemorrhage, and that it is very convenient to insert radium at the time; the whole treatment thus being completed in a few days. (2) That the action of radium may be on the endometrium and may cause less depression of ovarian activity. As I have said, I think the weight of evidence is opposed to this theory.

In favour of x rays it may be said that: (1) there are no complications such as discharge due to endometrial destruction; (2) in cases of diabetes, cardiac disease, etc., when a diagnostic curettage must be omitted, no anaesthetic is necessary; (3) there is no danger of embolism or damage to an adherent loop of intestine; (4) even in cases of pelvic inflammation x rays can be used if given slowly and carefully; (5) there is no reason why x rays should not be employed after a preliminary dilatation and curettage. In addition, radium causes a varying degree of discomfort, nausea, and perhaps vomiting during the time it is in the uterus. This is avoided by the use of x rays, although such symptoms may also occur if x-ray treatment is carried out too quickly—for example, in a single treatment.

To sum up, I think that when both methods are available x rays are to be preferred.

TECHNIQUE AND DOSAGE

Radium.—In England probably the most common method is the one I have described—namely, the use of an intra-uterine applicator containing 50 mg. for forty-eight hours, giving a dose of 2,400 mg.-hours, with a filtration of not less than 1.5 mm. of platinum or its equivalent. Variations of this have been 75 mg. for thirty-six hours or 100 mg. for twenty-four hours, with the object of reducing the time the radium is in the uterus and thereby curtailing the nausea and discomfort. I think, however, that the greater intensity of radiation is more likely to increase the symptoms while the radium is in position. In America the doses have usually been somewhat smaller, but the filtration has been less; 1,800 mg.-hours with 1 mm. platinum filtration is about the maximum. Norman White (1933) showed that recurrence may arise after this dosage, and advised as much as 3,000 mg.-hours with 1.5 mm. platinum, or equivalent, filtration. In our series 2,400 mg.-hours was successful in all but two cases, and these patients were big women, both only 38 years old. In France it is common to use radium packed into the lateral fornices of the vagina as well as the intra-uterine dose, which is considerably decreased. This may be advantageous in that the radium is placed closer to the ovaries and the sequelae of endometrial destruction are diminished; the disadvantage is that vaginal contraction may occur.

X Rays.—Many varieties of technique have been described that aim at the production of amenorrhoea in cases of menorrhagia, and all have met with a high percentage of successes because sterilization in women approaching the menopause can be achieved by a very moderate dose of radiation received on the ovary. This in some cases has resulted in the use of the lower kilovoltages for this purpose, even though the majority of therapeutic x-ray machines in this country are capable of working at about 200 kV. A kilovoltage of 150 or even lower will produce amenorrhoea with a fair degree of certainty, but the dose necessary is close to the skin

tolerance, and there is more danger of causing skin damage than with an adequately filtered beam generated at 200 kV. Sterilization can be produced in women over 35 by an irradiation carried out in one day, but, as previously stated, this may give rise to a considerable amount of nausea and vomiting, which will be entirely avoided if the dose is fractionized and spread over a week to ten days. The effect is also more certain if the period of irradiation is prolonged. A method which we have found suitable is to use 200 kV with a Thoreus filter and a focal skin distance of 50 cm.; to irradiate three fields, one anterior and two postero-lateral, each about 10 by 15 cm.; and to treat daily, giving a dose of 300 r to each field in succession for a total of nine treatments—that is, three treatments of 300 r measured on the skin to each area. This results in a dose of 700 to 900 r to the ovaries. In very big women it may be necessary to increase the surface dose.

Menopausal symptoms such as hot flushes follow the production of amenorrhoea by either radium or x rays, and have been investigated by various workers—Donaldson and Moore Patterson (1938), Malpas (1937), Miss Martindale (1938). There is general agreement that they do not vary either in nature or in severity from those accompanying either the natural or the surgically produced climacteric.

II. Bleeding Associated with Fibroids

In uncomplicated cases of uterine haemorrhage associated with fibroids occurring in women about or over the age of 40 radiotherapy is the treatment of choice. Bleeding is controlled as rapidly and with the same sureness as in menopausal menorrhagia, and the fibroid decreases markedly in size in two to three months. In the case of large fibroids which may not entirely disappear the remnant causes no symptoms. The treatment is carried out in the same way as for menopausal menorrhagia: there are the same indications for the choice of x rays or radium, except that, in the case of fibroids, x rays seem to be more definitely indicated because the distortion due to the tumour may cause the ovaries to lie at an increased distance from the endometrium, with consequent diminution of the dose received from the intra-uterine radium.

Radiotherapy should not be used in the treatment of fibroids in young women unless there is some factor, such as cardiac disease, which makes the risk of surgery too great. The results are uncertain, and successful treatment invariably produces menopausal symptoms. Other contraindications to radiotherapy for fibroids are: (1) pressure symptoms—for example, interference with micturition through pressure on the urethra when a very rapid result is necessary; (2) evidence of degeneration of the fibroid; (3) very large fibroids. These latter tend to show incomplete regression and are more likely to undergo degeneration. Many radiotherapists do not agree that the size of the fibroid is a contraindication. Finzi (1933) in particular states that some of his most striking results have been in cases with very large tumours, in which operation would have meant considerable risk and prolonged convalescence.

III. Menorrhagia in Young Subjects

This is a field in which the indications for radiotherapy are much more debatable. In the past it has been accepted generally that these patients should be treated by hysterectomy, with preservation of the ovaries, if more conservative treatment has failed. A considerable amount of work has been done, however, the object being to produce a temporary cessation of bleeding by giving a

dose of radiation which would destroy the mature Graafian follicles but would not be sufficient to damage the undeveloped follicles; so that menstruation would become established after a period of amenorrhoea lasting for some months, and there would be a possibility of future pregnancy.

Phillips has tabulated the records of 165 patients, in 128 (77.5 per cent.) of whom normal menstruation was restored. These were mostly adolescents and young women under the age of 25. The treatment was by radium in every instance, and a small dose averaging under 500 mg.-hours was given. It would appear that this treatment is still in the experimental stage, and that the dosage cannot yet be expressed numerically with accuracy. The question as to the liability to subsequent normal pregnancy is even less clearly defined.

Corscaden, Kasabach, and Lenz (1938) record sixty-nine further cases which received a substerilizing dose of radium or x rays for menorrhagia, fibroids, or dysmenorrhoea. Eleven pregnancies occurred among six women in this series: five patients aborted; four children lived beyond infancy, and two died at the age of 6 weeks and 6 months. This is only a small series, and the larger numbers of Murphy and Goldstein (1929) and of Miller *et al.* (1936) indicate that preconceptional irradiation should have no harmful effect on subsequent pregnancies, and that certainly it does not cause any increase in the percentage of abnormal children and monsters. It may be thought that the four surviving children in Corscaden's series are sufficient indication that this method of treatment is of value: it is obviously much to be preferred to the alternative of hysterectomy in those cases of severe bleeding which sometimes occur at puberty. It should only be used, however, when all else has been tried, and patients should be warned of the possibility of permanent menopause which may result (with the present state of our knowledge) in a certain proportion, especially of those aged 30 and over.

Further, if one accepts the action of radium as being mainly on the ovary—and it appears that this is the only way that the greater difficulty in sterilizing young women can be explained—it would seem advisable to use x rays rather than radium: the dose to the ovaries can be assessed with greater accuracy and there is less damage to the endometrium, with consequently a greater chance that an impregnated ovum can be retained.

Small-pox has become an extinct disease in Poland, where the law on compulsory vaccination and revaccination is strictly enforced. Complications of vaccination are rare, and no cases of post-vaccinal encephalitis have so far been reported in Poland. In many towns where immunization against diphtheria is also compulsory protection against the two diseases is carried out at the same time.

THE TREATMENT OF NON-MALIGNANT UTERINE HAEMORRHAGE*

BY

BEATRICE M. WILLMOTT, M.B., F.R.C.S.,
D.M.R.E.

Honorary Surgeon and Radium Officer Birmingham and
Midland Hospital for Women

The treatment of non-malignant uterine haemorrhage in women approaching the menopause—the only class of case which I propose to consider—calls for a nicety of judgment which is, I think, ideally to be expected of the gynaecologist with special training in radiotherapy. Those in whom the surgical instinct predominates habitually subject women to major operations which, as I hope to show, can be avoided in many cases by the substitution of radiotherapy. Radical operation entails a primary mortality which is inseparable from hysterectomy; moreover, in every practice there occur, not infrequently, cases which for one reason or another are bad surgical risks—heart and lung disease, obesity, and so forth. On the other hand, the indiscriminate use of radiotherapy will in some cases involve the retention of a dangerously unhealthy uterine cervix, and in other cases, notably submucous fibroids, a liability to sloughing, with the possibility of catastrophe.

It is my practice to use total abdominal hysterectomy in all cases showing an advanced degree of chronic cervicitis, in the presence of large fibroids causing symptoms, unless myomectomy is indicated, and in those judged to be submucous. I avoid sterilizing operations so far as possible by trying medical treatment and sometimes curettage in women who desire to add to their families. In all other cases, including bad surgical risks, I prefer to use radium. Deep x rays are not at the moment available for my patients, so in the field of radiotherapy radium for me is Hobson's choice.

My impression has been that radium is most valuable in suitable cases, and for the purposes of this discussion, and with the permission of my colleagues of the Birmingham and Midland Hospital for Women, I have investigated the results of cases treated in that hospital during the years 1935 to 1937. These results I propose to present here.

Analysis of Cases Treated with Radium

Of 226 patients presumed to have been reached by a questionnaire 199 replied. I have felt justified in assuming that those who failed to reply are a fair sample of the whole; probably any woman with a grievance would have seized this chance of airing it.

Diagnosis.—The cases are classified as follows: subinvolution seven, metropathia haemorrhagica twenty-two, fibroids twenty. Two cases are included in which radium was applied to bring about sterilization. The remaining 148 cases I have not attempted to diagnose scientifically, but have used the term "chronic metritis."

Dosage.—A single 40-mg. or 50-mg. needle was used, with screenage equivalent to 1 mm. of platinum. The needle was left *in situ* for from twenty-four to forty-eight hours, in a few cases for seventy-two hours. The dosage of radium element varied from 960 to 3,600 mg.-hours, the great majority receiving about 2,000.

* Read in the Section of Radiology at the Annual Meeting of the British Medical Association, Plymouth, 1933.

Results

The results I will discuss under headings, including the usual objections to the use of radium therapy—namely, the complaints of discharge and pain following the application.

Bleeding.—A total of 187 cases (94 per cent.) have complete amenorrhoea. Of the twelve cases in which bleeding was not entirely arrested, hysterectomy followed in two cases; two others are still suffering from menorrhagia. The cases in which hysterectomy was performed were those of chronic metritis at ages 33 and 34, the doses being 1,800 and 1,200 mg.-hours, and it seems probable that a larger dose or a further application would have brought about a cure. A case of chronic metritis at the age of 38 (dosage, 1,920 mg.-hours) had no relief at all, and a case of a fairly large fibroid at 48 (1,920 mg.-hours) is in a similar condition. Three women state that they now have normal periods; they are aged 34 (dose 1,800 mg.-hours), 37 (1,200 mg.-hours), and 35 (1,200 mg.-hours). Five state that they have had a period occasionally. Only four patients (2 per cent.), therefore, are dissatisfied on account of abnormal bleeding. As regards the cessation of bleeding after the treatment in the remaining 187, ninety-five had no further loss. In forty-three the bleeding ceased during the first month; it continued longer than a month in fifteen, the longest time being seven months. Thirty had from one to four periods after the operation; two have an occasional period; one had a single slight loss, and one lost for eleven weeks nineteen months after treatment.

Discharge.—This is a most difficult symptom to evaluate, especially as it was present in many cases before the treatment. Eighty-two patients (41 per cent.) replied that they noticed no discharge; thirty-two had a slight discharge, and eighty-one a moderate amount, lasting for varying periods. Two had a profuse discharge—one for a month only; the other, a patient who had no relief from her menorrhagia, still discharges freely. The one significant point I have been able to make on the subject of discharge is that only two patients complain of discharge under the heading "Ill effects of the treatment."

Pain.—It is even more difficult, from the answers to a simple questionnaire, to reach satisfactory conclusions on this symptom. In 138 cases (69 per cent.) there was no pain at all. Pain was slight or moderate in a further forty-eight. Fourteen cases (7 per cent.) had what they consider severe pain for periods of from a few days up to three months. One woman says she had severe pain for a year. Again, it is significant that only one woman mentioned pain in reply to the question on "Ill effects."

Ill Effects.—No ill effect at all was noticed in 123 (62 per cent.) of the cases. Of the remaining seventy-six, seventeen (8.5 per cent.) mentioned definite menopausal symptoms, such as sweats and flushes—a surprisingly small proportion. Three others noticed an increase in weight, seven had headaches, and fifteen complained of weakness and "nerves." Two complain of dyspareunia (I have not been able to examine these patients), one seems to have had a femoral thrombosis, one cystitis, one severe diarrhoea, and one had thyrotoxicosis later, of which the abnormal haemorrhage was probably an early symptom. The remaining few complaints were irrelevant.

Results from the Patients' Point of View.—In response to the question "Was the result of the treatment entirely satisfactory to you?" 184 (92.5 per cent.) replied "Yes," and twenty-eight patients were moved to add notes expressing extreme satisfaction and gratitude with varying

degrees of eloquence. Only fifteen (7.5 per cent.) were less than completely satisfied.

I entered upon this investigation with, I hope, an unbiased mind, and I have been greatly impressed by the almost uniformly satisfactory results. They seem to me striking evidence of the value of radium therapy in selected cases of uterine haemorrhage in women approaching the menopause. I would only add that of 411 cases so treated during the past four years the only death was that of a patient who afterwards proved to be suffering from purpura, a record which I am sure could not have been equalled had radical measures been adopted in all these cases.

DANGER OF PRIMARY ABDOMINAL TUBERCULOSIS IN CHILDREN

BY

STEFAN ENGEL, M.D.

RUBY O. STERN, M.D.

*Sebag-Montefiore Research Fellow, Hospital for Sick
Children, Great Ormond Street*

AND

G. H. NEWNS, M.D., M.R.C.P.

*Physician to the Bolingbroke Hospital; late In-patient Medical
Registrar and Pathologist, Hospital for Sick Children,
Great Ormond Street*

The object of this paper is to present a series of cases of primary abdominal tuberculosis in children which terminated in a fatal meningitis, and to emphasize certain points in order to direct the attention of practitioners to the danger of primary abdominal tuberculosis in the child.

Primary tuberculosis of the lung has been extensively studied in children, and it is well known that in this form of tuberculosis the greatest risk to life results from generalized dissemination of the disease, usually manifested by a terminal meningitis. This risk is particularly great in the first three years of life, so that the prognosis in a case of primary tuberculous infection of the lung depends mainly on the age of the child.

Investigations into the fate of children infected with primary abdominal tuberculosis have been chiefly centred on identification of the type of bacillus responsible, human or bovine, or to the percentage incidence as compared with that of primary pulmonary infection, notably by Griffith (1932, 1934, 1937, 1938) and Blacklock (1932, 1935). Many significant facts have emerged from their investigations, two of the most important for the purposes of this paper being, first, that in 80 to 82 per cent. of cases of primary abdominal tuberculosis the infection is due to the bovine type of bacillus, and, secondly, that generalized dissemination takes place from a primary abdominal focus of infection in a high proportion of cases (32.4 per cent. in Blacklock's (1935) series of 372 cases).

For many years it was denied on the Continent that miliary tuberculosis could follow a primary abdominal infection, and only lately has this contention been refuted by the work of Griffith and Blacklock in this country and of Klereker (1931) in Sweden. The clinical importance of their investigations is even greater than is suggested by the figures quoted above, as these results were necessarily obtained by post-mortem examination, and, as will be seen later, the post-mortem figures do not nearly approximate to the total number of cases of miliary tuberculosis in children.

The Incidence of Primary Abdominal Tuberculosis

A survey of the last 3,214 post-mortem examinations at the Hospital for Sick Children revealed tuberculous meningitis as the cause of death in 284 cases—that is to say, this disease accounted for 8.8 per cent. of the necropsies. In forty-one (14.4 per cent.) of these cases the primary focus of infection was in the abdominal lymph glands. Stated differently, tuberculous meningitis resulting from a primary abdominal focus was responsible for death in more than 1.2 per cent. of over 3,000 necropsies. That this figure in no way represents the true mortality may be gauged from the fact that during the period 1933 to 1937 eighty-five children died in the hospital from tuberculous meningitis, but in only thirty-six of these were necropsies permitted—less than half the total number. (It is noteworthy that in the experience of one of us (G. H. N.) there is exceptional difficulty in obtaining permission to hold a post-mortem examination on children dying from tuberculous meningitis, in many cases because the child has been the only one.)

Criteria of "Primary Abdominal Focus" Infection

Our diagnosis of "primary abdominal infection" was based on enlargement with obvious tuberculous infection of the mesenteric lymph glands, with or without caseation, and complete absence of evidence of tuberculous infection of the bronchial or other mediastinal glands. No case was included in this series in which any enlargement whatsoever of the bronchial glands was recorded, or in which there were any tuberculous lesions of the lungs other than the miliary tubercles seen as a result of generalized dissemination of the disease.

Age and Sex Incidence

The next important feature is the age incidence. Former investigators have already stated that the highest incidence of primary abdominal tuberculosis falls in the first three years of life. The exact figures of this hospital were:

| | | | | | | | |
|-----------|----|----|---------|-----------|----|----|---------|
| 0-1 year | .. | .. | 4 cases | 3-4 years | .. | .. | 4 cases |
| 1-2 years | .. | .. | 23 " | 4-5 " | .. | .. | 3 " |
| 2-3 " | .. | .. | 2 " | | | | |

Here the facts only are stated; their significance will be discussed later.

A common and tragic history was that the child had been breast-fed for six to nine months and thereafter had had "ordinary milk diet." In one case, however, recorded in detail as an illustrative case, the parents were emphatic that the child had been given nothing but boiled milk and that there had been no contact with any possible source of human tuberculosis.

Our findings as regards the sex incidence were similar to those of Blacklock and Griffin (1935), who found that tuberculous meningitis following a primary abdominal lesion was commoner in boys than in girls. Twenty-eight of the forty-one cases occurred in boys and only thirteen in girls. Of the total 284 cases of meningitis 152 were in boys and 132 in girls, so that 18.4 per cent. of boys succumbed to meningitis following a primary abdominal lesion and only 9.8 per cent. of girls.

Clinical Features

It may be said that diagnosis of primary abdominal tuberculosis in the living child is almost impossible in the absence of such secondary lesions as tumour-like masses of glands, gross tuberculous peritonitis, or advanced ulceration of the intestine. The first sign of primary abdominal

tuberculosis is only too often the onset of meningitis. It was rare in our series to obtain a history of anything but malaise, irritability, with perhaps constipation or vomiting for a short time, very seldom for more than two weeks. Only in four cases was there a history of illness extending over a period of two months. One of these (Case III below) is quoted as an illustrative case. Two of the other three cases with a long history had frank plastic tuberculous peritonitis, the intestines being matted together by caseating glands and adhesions in the mesentery. In the fourth case a long-standing spinal caries affecting the second lumbar vertebra and complicated by a psoas abscess preceded the meningitis.

Unfortunately an x-ray examination, which is of such invaluable help, if conducted critically, in diagnosis of a primary lung infection, is of little use for the diagnosis of primary abdominal infection. It reveals only calcified glands, a residuum of the infection, when the disease process is no longer active and danger is past. In the present state of our knowledge we can only say that, as clinical diagnosis of the primary abdominal focus is impossible, prevention of the infection becomes of paramount importance.

Case I

J. C., aged 1 year 8 months, was quite well until two weeks before admission to hospital on June 4, 1937, when he became drowsy and disinclined to play. His appetite became poor. About a week later he had a convulsion and became unconscious. Since then he had been comatose and difficult to rouse. For several days he had vomited after meals. He was a normal full-term infant and was breast-fed (period not stated). There was no history of contact with tuberculosis. There was one other child, a boy aged 6 years, who was well. The parents were healthy.

On examination the child was comatose. The head was retracted. There was marked proptosis of both eyes. The optic fundi were normal. The Mantoux reaction (1 in 1,000) was strongly positive. The cerebrospinal fluid was examined on June 10, and contained 15 lymphocytes per c.mm., 95 mg. of protein per 100 c.cm., and 690 mg. of chlorides per 100 c.cm. No tubercle bacilli were seen. The chlorides fell terminally to 590 mg. per 100 c.cm. The child died a month after admission.

Necropsy Findings.—A typical tuberculous meningitis was present. There was a considerable degree of hydrocephalus. No tuberculomata were found in the brain. Many miliary tubercles were scattered throughout both lungs. There was no tuberculous infiltration of any of the bronchial or mediastinal glands. Miliary tubercles were present in the liver, spleen, and kidneys. A mass of enlarged tuberculous glands was situated in the mesentery. Caseation had not yet begun. No tuberculous ulceration was found in any part of the intestinal tract.

Case II

D. I., aged 1 year 6 months, was admitted to the Hospital for Sick Children on December 9, 1937. For two weeks he had had pyrexia and had lost his appetite. He had vomited occasionally. There was no history of contact with tuberculous patients. The other members of the family were healthy.

When admitted he was drowsy, with a temperature of 102° and a pulse rate of 128. There was neck rigidity, and a positive Kernig's sign was obtained on both sides. No papilloedema and no choroidal tubercles were observed. Examination of the cerebrospinal fluid showed 275 cells per c.mm., 2 per cent. being polymorphs and 98 per cent. lymphocytes; and 100 mg. of protein per 100 c.cm. Reduction of Fehling's solution was poor. Chlorides amounted to 670 mg. per 100 c.cm., and tubercle bacilli were present. The child died six days after admission.

Necropsy Findings.—Well-marked tuberculous meningitis was present. There was a considerable degree of hydrocephalus. A few miliary tubercles were found in both lungs. There was no tuberculous infiltration of any of the bronchial or mediastinal glands. Many miliary tubercles were present in the liver and spleen, but none were observed in the kidneys. There were one large and several smaller tuberculous glands in the mesentery. These had undergone caseation and were becoming liquefied. No definite tuberculous ulceration was found in the small or large intestine.

Case III

J. S., aged 1 year 3 months, was admitted to the Hospital for Sick Children on July 16, 1938. He had been well until two months previously, when he developed intermittent vomiting, lost his appetite, and became constipated. Ten days before admission he had three convulsions. Later he became drowsy and eventually relapsed into coma. There was no history of tuberculous contact. The parents were healthy. The child since early infancy had been fed on "accredited" milk, which the parents declared was always boiled.

The patient, on admission, was comatose and had Cheyne-Stokes respiration. The abdomen was retracted. A mass was felt near the umbilicus and another in the right iliac fossa. Early papilloedema was present, but no choroidal tubercles were seen. The cerebrospinal fluid was not under pressure; it was opalescent and slightly yellow; the chlorides amounted to 650 mg. per 100 c.cm.; and culture was sterile. The child died the day after admission.

Necropsy Findings.—There was only a thin fibrinous exudate containing a few miliary tubercles at the base of the brain and limited to the infundibular space. A few very small miliary tubercles were scattered throughout both lungs. There was no tuberculous infiltration of any of the bronchial or mediastinal glands. The spleen was slightly enlarged, and contained many rather large miliary tubercles. A few miliary tubercles were present in the kidney and liver. There was extensive ulceration of the mucous membrane of the last few inches of the ileum and of the caecum. The ulcers were irregular, and were situated transversely to the long axis of the gut. There were many miliary tubercles on the peritoneal surface. No ulceration was present in the rest of the small intestine or in any part of the large intestine. One large caseous tuberculous gland was situated alongside the second part of the duodenum and a large mass of tuberculous glands was present in the mesentery of the ileo-caecal angle. These glands were in various stages of caseation.

Some Points in Morbid Anatomy

Two of the above cases illustrate the salient feature of the morbid anatomy of tuberculous meningitis resulting from a primary abdominal focus—that is, the small size of the lesion in the abdomen which can give rise to a fatal meningitis. In many cases only *one* enlarged infected gland could be found in the mesentery, and no trace of ulceration could be discovered in the bowel. Reference has already been made to the few cases in which gross peritonitis or ulceration of the bowel was present. Widespread dissemination of miliary tubercles was almost invariable; only in three cases was there a meningitis without miliary tubercles in the viscera. Often only a few tubercles were scattered over the pleural surfaces of the lungs and on the surface of the liver, spleen, and kidneys; but in view of Blacklock and Griffin's series (1935), in which they found 27.8 per cent. of cases with meningitis following a primary abdominal lesion without generalized miliary tuberculosis, it is rather remarkable that only three similar cases (7.3 per cent.) should have occurred in our series.

A macroscopic tuberculoma was found in the brain in only one case, in which a hard mass the size of a cherry stone occupied part of the right crus and the floor of the third ventricle. The rarity of tuberculomata in meningitis

following a primary abdominal lesion contrasts with the frequency with which they occur in meningitis resulting from a primary lung infection; for in the whole series of 284 cases of meningitis, tuberculomata were present in thirty-five (12.3 per cent.).

Geographical Distribution

Both Griffith (1938) and Blacklock (1932) have pointed out that primary abdominal tuberculosis, owing to the high percentage of the bovine type of bacillus found in this form, is more prevalent in rural districts than in cities. It is noteworthy that in our admittedly small series of forty-one cases twelve children came from one particular county and from a radius in it of not more than thirty miles. Central London furnished only fifteen cases and "Greater London" another four.

Discussion

Our observations on a series of children who were investigated both clinically and pathologically afford striking evidence of the danger to which children are exposed by infection with primary abdominal tuberculosis. This danger may take the form of generalized miliary tuberculosis with or without a terminal meningitis, or, rarely, of an isolated fatal meningitis. The admirable work and statistical surveys of pathologists and bacteriologists such as Blacklock and Griffith in this country and Klercker in Sweden are apparently not fully appreciated by practitioners. This is the more deplorable because the mortality revealed by their studies and also by our investigations represents only part of the morbidity due to primary abdominal tuberculosis, which results also in many cases of "surgical tuberculosis."

One of the most important points with which we have dealt is the reflection of age incidence on the prognosis. We found that twenty-eight cases of the forty-one came to necropsy during the second year of life, and that no case occurred after the age of 5 years. In order to explain this age incidence many factors must be considered. It is possible that younger children are more susceptible subjects for implantation of the tubercle bacillus in the intestine, as it is well known that their intestines form a *locus minoris resistentiae* for many intestinal disorders which occur at this age. But a more likely possibility seems to be that in the very young there is *difficulty in localizing* the disease process. This opinion is supported by the parallel series of cases of generalized miliary tuberculosis with meningitis resulting from primary lung infection published by one of us (S. E.) in 1924 and 1930. In these cases failure of localization was revealed by anatomical evidence. In the younger children bronchial glands at a distance from those primarily draining the primary tuberculous focus in the lung were larger and much more often affected than in older children. The slight tendency for younger children to localize the tuberculous process was thus proved by ocular demonstration. It has not yet been possible to bring forward similar evidence in primary abdominal infection owing to the small number of cases personally observed.

Another point to be mentioned is the effect of the difference in feeding which takes place during the second half of the first year. This change from breast milk to cow's milk could be held responsible for the high incidence of fatal cases in the second year of life. We consider that the infection originates in this way in the vast majority of cases, but that the high mortality at an early age is due to the deficient power of localization mentioned above. It is common knowledge that primary abdominal tuber-

culosis is most often due to the bovine type of bacillus which is conveyed in milk. The researches of Blacklock and Griffith leave no doubt on this point, as they found the bovine type of bacillus in 80 to 82 per cent. of cases with primary foci in the abdomen. We are therefore entitled to assume that in our cases also the bovine type of bacillus predominated. This assumption is sustained by the fact that a majority of the children came from rural areas where children are more often fed on raw milk.

It may be remarked that in Case III the parents declared that the child had been given only boiled milk. The possibilities in this case are, first, that the infection was of the human type, which is rare; and, secondly, that the milk had been insufficiently or not always boiled. To omit to boil milk properly on a single occasion is quite sufficient to allow the tubercle bacillus to enter the body and give rise to infection.

Conclusions

Primary abdominal tuberculosis is a commoner disease in children than is generally supposed, and the true incidence is much higher than post-mortem figures indicate.

In primary abdominal infection, as in cases with a primary lung infection, the prognosis depends on the age of the child: the younger the child at the time of infection the worse the prognosis.

We are unable to accept the current view that primary abdominal tuberculosis can be more lightly regarded in children than can a primary lung infection: the bad prognosis in young children refutes this view. Diagnosis in cases of primary abdominal tuberculosis in the living child is extremely difficult; consequently early treatment is rarely possible. Prevention of infection is therefore all-important. Many cases of tuberculous meningitis, miliary tuberculosis, and crippling deformities could be prevented. We should endeavour, as an ideal, to secure for children milk from tuberculin-tested herds only, but at present it is impossible to provide this for the whole population. Therefore the greatest measure of protection is afforded by milk which has been boiled or efficiently pasteurized.

We wish to thank Dr. D. N. Naharro, Director of the Pathological Department, Hospital for Sick Children, for the interest he has taken in our work, and the honorary medical and surgical staff of the hospital for permission to use their case reports and post-mortem records.

APLASTIC ANAEMIA WITH COMPLETE RECOVERY

BY

T. H. BOON, M.D., M.R.C.P.

Medical Registrar, Royal Victoria Infirmary Newcastle-upon-Tyne

When treating a patient with aplastic anaemia it is difficult to decide as to how long it is worth while keeping him alive by repeated blood transfusions in the hope that his bone marrow will ultimately revive and so maintain his cure. There are types of so-called idiopathic aplastic anaemia in which the bone marrow fails to recover and the disease is progressive and fatal. Blood transfusion probably does no more than postpone their death by a few months. There are other types of aplastic anaemia, usually the result of poisoning by drugs, in which the bone marrow quickly recovers its function and effects an automatic cure with or without the aid of a few blood transfusions. It is between these extremes that we are faced with the difficulty of deciding the number of transfusions to be given.

The case whose story is reported here is that of a man with aplastic anaemia following salvarsan therapy who in 1935 was kept alive for nine months with blood transfusions and is now (three years afterwards) in good health. At first no history of treatment by salvarsan was obtained, and in the absence of any apparent exposure to a noxious drug he was regarded as suffering from idiopathic aplastic anaemia. With the haemoglobin falling to 18 per cent. and the patient almost blind from retinal haemorrhages, there appeared to be no hope of recovery. He continued in this state for five weeks while transfusions were given to him two or three times weekly. In all, twenty-five transfusions were given in nine months.

Case History

The patient, a confectionery baker aged 50, began to complain of lack of energy and shortness of breath on exertion, and in April, 1935, his friends noticed that he was getting pale. A blood count done at that time showed 50 per cent. haemoglobin with colour index 1.1, and in spite of intensive oral and intramuscular liver therapy his condition rapidly became worse. He was first seen in May, and was admitted to hospital on the 30th of that month. He was then in a very critical condition, with dyspnoea on the slightest exertion. His mental processes were distinctly sluggish, his manner morose, and the history was given in a distant and hesitant manner which did not lead one to place much reliance on his statements. There were widespread haemorrhages into the skin and mucous membranes, and these were so thickly scattered in the retina that he was scarcely able to see. There were a few superficial ulcers with their sloughs on the buccal surface of the lower lip. Apart from some distension of the bladder, which could be palpated without discomfort, and absent ankle-jerks, examination was negative. The Wassermann reaction was very weak positive, and the van den Bergh normal, and radiographs of the femora revealed no encroachment on the medulla.

A blood examination resulted as follows: red cells, 1,380,000; haemoglobin, 23 per cent.; colour index, 1.02; reticulocytes, 0.6 per cent. The red cells were normal in shape, size, and colour. There was a slight amount of anisocytosis, but no poikilocytosis or polychromatophilia. No early forms were seen. Platelets numbered 38,600 (over 500 erythrocytes), and the white cells 2,187. The differential count showed: polymorphs, 16 per cent. (350 per c.mm.); lymphocytes, 72 per cent. (1,575); monocytes, 9 per cent. (197); eosinophils, 1 per cent. (22); basophils, 1 per cent. (22); myelocytes, 1 per cent. (22). The lymphocytes were mainly large in character. No primitive forms were seen. The

The regulations governing the award of Commonwealth Fund Fellowships have been amended since the publication in the *Journal* of October 15 (p. 804) of the announcement regarding the fellowships. The chief alterations are as follows: Candidates must be unmarried and must not have attained the age of 30 on September 1 of the year of award; fellowships are vacated by marriage; they are open to men only; and are tenable for two years. Readers of the *British Medical Journal* who are interested are advised to apply to the secretary of the Commonwealth Fund Fellowships, 35, Portman Square, W.1, for copies of the revised regulations.

Arneth count over 16 polymorphs showed a slight shift to the left: young forms, 5; 2 lobes, 9; 3 lobes, 2.

The patient's doctor was unaware that the man had ever had any serious illness or any treatment during the few years he had known him, and the patient was unable to give any reliable evidence regarding himself. It subsequently transpired that in 1926, when living elsewhere, he sought medical attention for incontinence of urine, and was found to have a positive blood Wassermann reaction. He received treatment during the subsequent four and a half years, at the end of which time he was discharged symptom-free but with the Wassermann reaction still positive. Details of treatment before July, 1928, are not available, but subsequent to that date he received three doses of 0.45 gramme of N.A.B., four of 0.6 gramme of N.A.B., six of 0.6 gramme of stabilarsan, and thirty-eight of 1 grain of mercury.

In July, 1928, symptoms returned, and treatment was resumed, being continued until December, 1934. During this time he received four doses of 0.45 gramme and five of 0.6 gramme of N.A.B. Jaundice then developed, and no treatment was given until March, 1935, from which date to the onset of symptoms six doses of 0.45 gramme of N.A.B. were administered, with no apparent ill effects other than slight loss of weight.

On account of the patient's condition on admission and a further fall of haemoglobin to 18 per cent. and red cells to 750,000 in the next week in spite of 18 oz. of blood being received as three transfusions, a hopeless prognosis was given. Intramuscular injections of pentose nucleotide were without effect on the white cell count and were soon discontinued, as the patient complained bitterly of pain at the site of injection. It was decided to see if recovery of the bone marrow would occur with the blood at a higher level, and accordingly ten transfusions of up to one pint were given in the next four weeks. During this period a remarkable change took place in the patient's mental and physical condition. He became cheerful and joelular, was able to get up and go about in comfort, and vision was restored to normal. No haemorrhages were now visible in the retina, and the blood count was as follows: red cells, 4,320,000; haemoglobin, 68 per cent.; reticulocytes, 0.6 per cent.; white cells, 4,375; polymorphs, 12 per cent.; lymphocytes, 84 per cent.; monocytes, 4 per cent.

At no time during this period did the reticulocytes exceed 1 per cent. The patient was discharged with instructions to take things very quietly and avoid physical exertion. One month later the haemoglobin fell to 38 per cent., but he still felt fairly well, and was able to carry out light supervisory work. Regular transfusions of one pint at intervals of three weeks were begun, and by this means haemoglobin was kept in the region of 50 per cent. He was transfused as an out-patient, and no untoward reactions were experienced, except on one occasion when loss of consciousness and an epileptiform convulsion occurred towards the end of a transfusion. The patient was then admitted for a few days, and an itching urticarial rash appeared three days after the transfusion. The blood was from a donor who had been used three months previously, and had been given at the same rate and in the same manner as on other occasions—citrate blood through a No. 12 hypodermic needle with a two-way syringe. The blood of two polycythaemic patients with haemoglobin 130 to 140 per cent was used on several occasions, but had to be diluted with saline to facilitate passage through a No. 12 needle.

Throughout this period the red blood cells showed a good deal of anisocytosis and the colour index remained high. At no time did the reticulocytes exceed 1 per cent. Platelets were about 40,000; the white blood cells were 1,500 to 4,000, with polymorphs less than 20 per cent. and many of them bilobed.

In March, 1936, owing to thrombosis of his only good vein and increasing difficulty in using the small superficial ones, it was decided to see if he could maintain himself at a low level. At first a slight fall occurred, but after several weeks the haemoglobin began to rise at the rate of 2 to 3 per cent. a week. Reticulocytes varied from 2 to 6.3 per cent.

In April, 1937, the count was: red cells, 4,110,000; haemoglobin, 99 per cent.; colour index, 1.2; white cells, 7,700. In August, 1937, it was: red cells, 4,880,000; haemoglobin, 105 per cent.; colour index, 1.07; white cells, 6,000; platelets, 214,000; polymorphs, 25 per cent.; lymphocytes, 52 per cent.; monocytes, 2 per cent.; basophils, 1 per cent. Undifferentiated, 18 per cent.; myelocytes, 2 per cent.; the red blood cells showed moderate anisocytosis.

When last seen, on December 28, 1937, the patient appeared quite normal, had had no further nervous symptoms, and the blood count was as follows: red cells, 4,600,000; haemoglobin, 92 per cent.; reticulocytes, 0.4 per cent.; white cells, 6,800; platelets, 370,000. At the present date he is known to be still well and at work.

Commentary

A case showing marked diminution in all the cellular elements of the blood following considerable arsenamine therapy is recorded. Fortunately the anaemia due to aplasia in this case was not increased by haemorrhage from the mucous membranes, as seen in a recent case of aplastic anaemia due to gold therapy for rheumatoid arthritis in which a fatal haematemesis occurred.

Despite a fall to 18 per cent. haemoglobin and 750,000 red cells recovery has occurred, and the patient is apparently normal more than two years after the last transfusion.

In the cases reviewed by McCarthy and Wilson (1932) that with the lowest level—one million—recovered, as did Imrie's (1935) case with 840,000 red cells and 17 per cent. haemoglobin. The former authors concluded that the drug and dose used made little difference to the prognosis, but the shorter the period between the last dose and the onset of symptoms the better the outlook. The thirty-four cases they described and collected from the literature showed a mortality of 83 per cent.

During the period that the blood level was kept up by transfusions there was no evidence of spontaneous recovery, the haemoglobin always being about 40 per cent. immediately before and 50 per cent. immediately after a transfusion.

Within a few weeks of ceasing transfusions there was an increase of reticulocytes and a gradual rise of red cells. The colour index remained high until a normal level was reached, and granulocytes lagged behind in their recovery.

There seems no doubt that without repeated transfusions the case reported would have rapidly proved fatal.

In all 418 oz. of blood were given as twenty-five transfusions.

I am indebted to Dr. J. C. Spence for allowing me to treat this case and for many helpful suggestions.

All applications for fellowships in connexion with the Finney-Howell Research Foundation must be filed in the office of that Foundation, 1211, Cathedral Street, Baltimore, Maryland, U.S.A., by January 1, 1939; the awards will be announced on March 1. This Foundation was created to intensify research into the cause or causes of cancer and its treatment. Ten such fellowships were awarded in 1938; each carries an annual stipend of 2,000 dollars, and may be renewed in two successive years. Applications are to be made on the forms supplied by the secretary of the Foundation at the above address.

TRIPHENYL ETHYLENE TESTED ON
CAPONS

BY

A. M. HAIN, D.Sc.

(From the Institute of Animal Genetics, Edinburgh University)

It has been shown by Robson and Schönberg (1937) that the synthetic substance triphenyl ethylene is highly oestrogenic when tested on ovariectomized mice; its ability to inhibit the specific effects of progesterone on the endometrium and muscle of the rabbit's uterus (Robson, 1938) demonstrates that it possesses many of the attributes of oestrin. Since oestrin also has a typical gynaecogenic action in that it causes hen-feathering in the capon (Juhn and Gustavson, 1930), it was suggested to me by Dr. J. M. Robson that the ability of triphenyl ethylene to induce a similar effect might be examined. Tests made on old English game capons (bantams) of the black-red variety produced no change in feather-colouring when 1 gramme of substance was injected in two days. It was found, however, that neither do such birds react to 1 mg. of oestrone of the international standard, and in the experience of Dr. Parkes (personal communication) they are comparatively insensitive to oestrin.

When a brown Leghorn capon was injected with a total of 0.8 gramme of triphenyl ethylene in two days a very marked reaction was obtained in both the colouring and the structure of the feathers. Thus, triphenyl ethylene possesses in common with another synthetic compound—diethylstilboestrol (Dodds, Lawson, and Noble, 1938)—oestrogenic and gynaecogenic activity.

The combs of capons injected with 0.8 and 1 gramme of triphenyl ethylene showed no increase in size but actually a slight regression on their previous minimum. A similar absence of effect was observed when 1 gramme in arachis oil was smeared on the comb of another capon. When the equivalent of approximately 0.5 gramme was smeared on the comb of a capon which was at the same time being injected with 1.5 mg. of standardized androsterone there was no inhibition of the response to androsterone.

Summary

1. Triphenyl ethylene causes hen-feathering in the brown Leghorn capon, as does oestrin and diethylstilboestrol.

2. In the amounts used it had no effect on old English game bantams (black-red), which have a low sensitivity to oestrin.

The expenses of the above investigation were defrayed by grants from the Medical Research Council.

During the past twenty-four years Dr. T. Wilson Parry has devoted much of his spare time to the study of primitive surgical holing (trephining or trepanning) of the human skull, and has published in all seventeen papers on this branch of medical history. He has now presented to the Library of the British Medical Association reprints of these contributions in pamphlet form, which can be consulted there by members interested in the subject.

Clinical Memoranda

Sulphanilamide in Climatic Bubo

Paradenitis venerea (climatic bubo or lymphogranuloma inguinale) is an uncommon disease in Great Britain, and the majority of the cases met with here are seen by the venereal diseases officers in the larger seaports. In the past the treatment of this condition with antimony compounds has been disappointing, and in the only case I have seen treated with vaccine the result was unsuccessful. The cases which reported for diagnosis before the infected glands had broken down have responded satisfactorily to surgical excision, but unfortunately the disease is usually further advanced when first seen and is characterized by extensive adenitis, inflammation of the adjacent tissues, sinus formation, and even involvement of the thigh and abdominal wall. The treatment of such cases has, in my experience, been disheartening to patient and doctor alike, and has required several dressings daily over a period of some months before healing of the sinus has been effected. It may be of interest, therefore, to record the following case, which satisfies the criteria necessary for a diagnosis of climatic bubo, and in which the response to chemotherapy with sulphanilamide has been very encouraging. In this connexion it is of interest to note that Fritz Bär (1938) has studied the experimental action of prontosil album in lymphogranulomatous meningo-encephalitis in mice, and mentions that Gjurić (1938) has recently reported successful results in the treatment of paradenitis venerea with prontosil album and also with a combination of prontosil album and foudadin. Kubitzki (1938) recorded a prompt fall of temperature and local improvement in cases treated with injections of prontosil.

CASE REPORT

The patient, a seaman aged 28, developed a small painless and non-tender swelling in the left groin three days after exposure to infection. A fortnight later the swelling had increased considerably and was then tender and painful. At no time was a genital sore noted. He attended the Seamen's Dispensary, Liverpool, where a diagnosis of climatic bubo was made and admission to hospital advised for excision of the infected glands, but unfortunately the patient refused to accept this advice. The Wassermann reaction at this visit was negative.

Six weeks after the onset of the adenitis the patient came under my observation when he was admitted to the V.D. wards, Mill Road Infirmary, Liverpool. On admission he felt and looked ill, and presented extensive inflammation and matting of the left inguinal glands. The inflammation also affected the tissues adjacent to the infected glands, involving an area which overlapped the left inguinal canal and extended below Poupart's ligament well into the base of Scarpa's triangle. The bubo had already broken down, and a copious, seropurulent, odourless discharge was draining through two small sinuses. There was no evidence of a genital sore or scar, and a tentative diagnosis of paradenitis venerea was subsequently confirmed by a positive Frei test. The Wassermann reaction was again negative, and an intradermal test with dmeclos vaccine produced no reaction.

Encouraged by the beneficial results of sulphanilamide therapy which I have obtained in cases of chancroidal ulceration, I decided to use this drug in the present case. The patient received 5 grammes daily for two days, 3.5 grammes on the third, fourth, and fifth days, and 2.5 grammes on each of the following eight days. Glycerin and magnesium sulphate dressings were applied locally, and four days later the bridge of necrotic tissue between the two sinuses was excised to facilitate drainage and permit packing the wound with gauze soaked in cod-liver oil. Under this regime the discharge

rapidly diminished and the wound showed evidence of healing. The patient was sent home in good health thirty-two days after admission, the sinus in the left groin being completely healed.

I wish to acknowledge my indebtedness to Dr. A. O. Ross for the findings obtained at the Seamen's Dispensary, Liverpool; and to Dr. L. Findlay, medical superintendent, Mill Road Infirmary, Liverpool, for permission to publish the case report.

Extra-uterine Intra-abdominal Pregnancy

Recent articles prompt us to record a case of extra-uterine intra-abdominal pregnancy in a native from the district of Mwanza, in the Lake Province, Tanganyika Territory.

CASE REPORT

The patient was admitted to the Mwanza Hospital on June 10, 1938, with a history of a nine-months pregnancy and, five days before admission, small pains and the loss of a little blood. The pains lasted for one day only. Previous labours (three) had been normal, but each infant had died after a few days.

At midday on the day of admission the patient was examined by the senior sister, and again at 4 p.m. by one of us. The notes read: "Vertex presentation, membranes ruptured; soft mass behind head (? twins), cervix two fingers dilated." The case was puzzling, so at 4.30 p.m. another examination was made, and the following was recorded: "Vertex presentation, membranes ruptured, cervix peculiar to touch, and a little bleeding after examination. The abdomen tense." Further examinations showed:

- 6 p.m.: Very slight pains; still losing liquor and very little blood.
9.15 p.m.: Very slight pains.
June 11, 2.20 a.m.: Slight pains; very slight loss of liquor. Has slept. Pulse 106.
7.15 a.m.: Losing a little blood; slight pains. Pulse 92.
10.15 a.m.: Refused intervention. No pain; liquor stopped. Pulse not good.
11.50 a.m.: No progress since yesterday; ? foetal heart heard. Slight blood loss. Blood malaria-positive.
2.30 p.m.: Consented to go to theatre. Condition very poor; but we were convinced that a laparotomy was needed, although a positive diagnosis had not been made.

Operation revealed an intra-abdominal pregnancy. The head had sloughed through the vaginal vault and presented as a vertex. The uterus, enlarged to the size of a five-months pregnancy, lay behind the head. The placenta was plastered on to the intestines. Peritonitis was advanced.

The child was a full-term female of good development, and weighed 7½ lb. The mother collapsed, and all efforts to resuscitate her and the infant failed.

COMMENTARY

The interest in this case lies in the vertex presentation of an intra-abdominal pregnancy. The head had found the pelvis, and intra-abdominal pressure had caused a necrosis. On removal of the foetus from the pelvis the large opening into the vagina could be easily seen and demonstrated.

There was no story of injury or interference by friend or witchcraft practitioner, but the doubt cannot be stilled that someone in the village community had attempted to deal with the condition.

TROPICAL DISEASES AND HYGIENE

Krankheiten und Hygiene der warmen Länder. By Professor Dr. P. Mühlens, Professor Dr. E. Nauck, Dr. H. Vogel, and Professor Dr. H. Ruge. Fourth edition. (Pp. 564; 431 figures, 6 coloured plates and 1 in half-tone, RM. 43; bound, RM. 45.) Leipzig: Georg Thieme. 1938.

Ruge, Mühlens, and Verth's well-known work *Tropical Diseases and Hygiene* now appears in a fourth edition revised and enlarged to 560 pages, with important contributions by Professors Nauck, Vogel, and Martini. It is a complete systematic treatise covering the whole field of tropical medicine and hygiene, and forms an important source of reference to the latest advances in these subjects. Professor Ruge is the author of sections dealing with climate and tropical hygiene, the bacterial diseases, tropical skin and venereal diseases, blood technique, sleeping sickness, Chaga's disease, tropical surgery, the tropical anaemias, and other matters. Professor Mühlens provides the sections on malaria (eighty-five pages), the leishmaniasis, amoebic diseases, and the spirochaetoses. The sections on yellow fever, dengue, sandfly fever, typhus, *Bartonella*, psittacosis, and deficiency diseases are by Professor Nauck; while Dr. Vogel is responsible for the section on parasitic worms (sixty pages) and Professor Martini for those on myiasis, sandflies, and poisonous animals. This indication of subject-matter suffices to show how large is the field now covered by tropical medicine; a detailed account of the enormous quantity of material included in the volume is impossible in the space of a short review. The section on tropical hygiene gives an interesting summary of the different climates of the earth, discusses acclimatization, clothing, construction of dwellings, dietary, water supply, hints on mode of life, care of children, and the general question of health and protection from disease in the Tropics. The section on malaria covers in condensed form practically the whole of this immense subject, and is a difficult one to comment on beyond saying that it is up to date and includes recent advances in treatment and in the principles of modern anti-malarial sanitation. The section on sleeping sickness provides a good clinical account of the different stages of the disease and its treatment, with brief but informed references to *Glossina*, the stages of the parasite as seen in the insect host, and methods used in control. Good short sections on kala-azar, Oriental sore, and American leishmaniasis are followed by a larger one on amoebic dysentery and other amoebic conditions, and this in turn by consideration of the now numerous spirochaetal diseases. In place of the one-time single heading of "relapsing fever" of the older textbooks, one now finds separately described the European (*Spirochaeta obermeieri*), the Spanish (*S. hispanica*), the Central African (*S. duttoni*), the North African (*S. berbera*), the Asiatic (*S. carteri*), the North American (*S. novyi*), and the South American (*S. neotropicalis*) forms, differing in the nature of the causal agent, the clinical features, and the vector concerned in transmission. Among diseases of leptospiral origin are useful sections on Weil's disease, Japanese seven-day fever, and rat-bite fever. Under rickettsial diseases are again many conditions, once unheard of or vaguely described, now clearly set forth with illustrative matter; and the same with diseases due to the bartonellas. Among the deficiency diseases is a section on epidemic

dropsy. Besides such major bacterial infections as plague, cholera and bacterial dysentery, and leprosy, there are accounts of tularaemia, psittacosis, and melioidosis. An interesting and well-illustrated section is that on poisonous animals.

The volume is one which as a work of reference on tropical diseases can scarcely be excelled. Accompanying the text are a number of well-executed coloured plates representing appearances of the different malaria parasites, forms of leucocytes, ova of worms, and other subjects.

SOCIAL HYGIENE

Empire Social Hygiene Yearbook, 1938-9. Prepared by the British Social Hygiene Council. Fifth annual edition. (Pp. 603. 15s. net.) London: George Allen and Unwin, 1938.

The *Empire Social Hygiene Yearbook*, which is now in its fifth year, contains a vast amount of information, not easily to be gathered from other sources, concerning the health, social, and educational services of the counties and county boroughs of Great Britain and Northern Ireland. Similar information is also afforded regarding the various States and provinces of India, the Dominions, and the Colonies. The preoccupation of the book is with the facilities for combating venereal diseases, but it is not limited to that subject, and the information which it gives with regard to district nursing, health visiting, ante-natal and child welfare centres, and provision for mental defectives is useful and well arranged. There are chapters, compact with information, on housing, maternity, illegitimacy, juvenile delinquency and probation, mental defect, tuberculosis, blindness, deafness, and crippledom. The section on the care of cripples is a relatively new feature. The number of cripples in England and Wales is stated to be nearly 200,000; at least eight of every thousand children under the age of 5 are cripples or require orthopaedic treatment, and of the population as a whole at least four in every thousand are in the same category. The analysis by counties and county boroughs includes this year a new section giving information about orthopaedic clinics. In some areas, particularly certain of the Welsh counties and Lancashire, these clinics are numerous and well attended; in others they are scarcely functioning, and from fifty-eight areas no information at all is vouchsafed. Local statistics of registered blind persons are also given, but here again many areas, including populous ones, furnish no returns. An article on the marriage laws sets out the changes made by the Matrimonial Causes Act. This year-book has well earned its place on the official desk and in the hands of those engaged in health and social services.

THE NEW CHEMOTHERAPY

Sulfanilamide Therapy of Bacterial Infections. With Special Reference to Diseases caused by Hemolytic Streptococci, Pneumococci, Meningococci, and Gonococci. By Ralph R. Mellon, M.D., Paul Gross, M.D., and Frank B. Cooper, M.S. (Pp. 398; 16 figures, 26 tables. 18s.) London: Baillière, Tindall and Cox. 1938.

The three years which have now elapsed since the public advent of prontosil have provided more than enough material for a book, and the volume *Sulfanilamide Therapy of Bacterial Infections*, by R. R. Mellon, P. Gross, and F. B. Cooper, has now been written. Actually less than half the text is a review of the chemistry, pharmacology, and experimental and clinical effects of sulphonamide compounds. The remainder is an account of the authors' own work on this subject, of which the main parts have been studies of the chemotherapy of experi-

mental streptococcal and pneumococcal infection and an analysis of the mechanism of sulphanilamide bacteriostasis. They explain the divergent results of *in vitro* tests in this connexion on the basis of "potentiation," by which is meant the combined damaging effect of sulphanilamide and something else. In their own experiments this other factor was saline used for culture dilution, which appeared to render streptococci more vulnerable than they were when broth was the diluent. There may be something in this idea, although its translation to *in vivo* terms is not an easy matter, and it would still hold good in principle even were the initial damaging agent not sodium chloride but copper: it is necessary to point this out because the source of the distilled water used in preparing the saline is not stated. Some of the arguments elaborated in this part of the book do not carry conviction: at least one is based on premises which have since been proved false, but it must be difficult to escape such penalties in writing at large on a subject undergoing such rapid development.

Freedom from the space restrictions which encompass the writer of a mere paper has evidently tempted the authors to dilate not only on their personal beliefs about chemotherapy but on other subjects remotely related, and there are descriptions of alleged bacterial mutation and a discussion of "fitness" in rabbits and men as indicated by capacity for heat regeneration, the connexion of which with the main subject seems rather forced. It is chiefly for its review of the experimental and clinical development of sulphanilamide therapy that this book will be valued: that review is clear, full, and competent. The clinician anxious to base his use of this drug on a better understanding of its properties, and the experimentalist who might otherwise have to search for a single fact among a score of papers in almost as many different journals, can each profit by reference to it.

COLLAPSE THERAPY OF PHTHISIS

Kollaps-therapie der Lungentuberkulose. By Hein, Kremer, and Schmidt. Two volumes. (Pp. 1,135; illustrated. RM. 116; bound, RM 119.) Leipzig: Georg Thieme. 1938.

The complaint is often heard that in spite of the advances made in the collapse therapy of pulmonary tuberculosis much of it still lacks a precise physio-pathological basis. The book by Hein, Kremer, and Schmidt (with three collaborators) should convince those who have not yet been won over to collapse therapy that in some clinics at all events such an accusation is not justified. What is by many still considered as belonging to theoretical or experimental fields is here seen applied in daily routine: for instance, tomography, kymography, and detailed investigation of the respiratory and cardiac functions. This is a far cry from the almost care-free embarking on a collapse operation after little more than inspection of a skiagram. But it required six authors, 1,100 pages, and over 1,000 illustrations to present a readable and logical account of methods and review the more important literature. Nevertheless it will be the costliness of these two volumes rather than their size which will discourage readers amenable to the conviction that phthisis is a curable disease from appreciating their contents.

A chapter on the morbid anatomical basis of collapse therapy by Wurm is followed by chapters on the morbid anatomical and clinico-radiological aspects of the healing of cavities by Wurm and Alexander respectively. In a section of nearly 200 pages, containing 200 illustrations, Schmidt and Gaubatz discuss the basis and methods of determining the indications for collapse therapy. The chapters on artificial pneumothorax and on oleothorax

are written by Schmidt, while Kremer deals with adhesion-section. In the second volume he discusses phrenic interruption, and is followed by Schmidt on "pneumolysis with subsequent extrapleural pneumo- or oleo-thorax." This is the best account so far published of this much-discussed operation, but it is debatable whether one should include in a standard textbook so full an account of a method the remote results of which are as yet unassessable.

Schmidt rightly insists that the procedure is not new, but has merely been taken up again recently with success. He brings out the indications clearly. The operation is indicated in the late stages of the "early" cavity (when intrapleural pneumothorax is impracticable owing to adhesions), and in certain patients with "tertiary" cavitation (for which up to the present plombage or thoracoplasty was carried out) when these operations are contra-indicated: extrapleural pneumothorax is associated with a slight operative mortality (2 per cent.), and affects the functional capacity of the lung only to an insignificant extent. These facts also support its use for bilateral collapse. Thus Schmidt's view on indications differs entirely (and in the reviewer's opinion rightly) from the view sometimes expressed—that extrapleural pneumothorax should always be carried out when possible in preference to thoracoplasty.

Kremer discusses plombage and shows that it retains a definite place in the treatment of cavities when thoracoplasty is contraindicated. Thoracoplasty is amply described by Hein in a section of 350 pages with 308 illustrations. The help that can be obtained from the use of tomography in connexion with this operation is well demonstrated. Several detailed tables of personal results are appended. In the final chapter Schmidt does a service in emphasizing the great importance of *Korrekturplastik* by devoting a special section to it himself; for too many surgeons, by not keeping rigidly in mind that the aim of collapse therapy is to render the patient sputum-negative, are apt to show timidity in tackling the sputum-positive patient on whom they have already performed a thoracoplasty.

The production of the book maintains the high standard of German medical publications, but the price will put the work out of reach of those who have not constant access to a good medical library. The illustrations, some of which are in colour, are excellent. The reproductions of the skiagrams leave nothing to the imagination. The typographical arrangement of the ample bibliographies, the usual one in German publications, must, however, be criticized; it will not encourage the reader to verify chapter and verse.

OTO-RHINO-LARYNGOLOGY

Diseases of the Nose, Throat and Ear: Medical and Surgical. By William Lincoln Ballenger, M.D., F.A.C.S., and Howard Charles Ballenger, M.D., F.A.C.S. Seventh edition, thoroughly revised. (Pp. 1,030; 576 figures, 30 plates, mostly in colour. 50s. net.) London: Henry Kimpton. 1938.

Practical Otolaryngology, Rhinology and Laryngology. By Adam Edward Schlanser, M.D. (Pp. 315; 81 figures. 21s. net.) London: Henry Kimpton. 1938.

Ballenger's *Diseases of the Nose, Throat and Ear* has become a standard American textbook, and the seventh edition is now published. The general style remains the same, but there has again been some rearrangement, and some new sections, such as those on physical therapy and on petrositis, have been added. The chapters on endoscopy at the end of the book by Dr. G. Tucker and Dr. C. L. Jackson again form a valuable feature. It was suggested in a former review that the practice of introducing sections

by independent authors might be extended with advantage. Dr. J. M. West describes the management of dacryostenosis, but otherwise this plan has not been followed to any extent, so that the opportunity of thorough revision of such chapters as those on malignant disease has been missed. The general excellence of the book, especially of the section on the ear, will no doubt maintain its popularity, but this edition provides no striking novelty, and some parts which are now out of date might have been eliminated.

Practical Otolaryngology, Rhinology and Laryngology is a manual written by Colonel Schlanser of the Medical Corps, United States Army, quite suitable for general use but directed chiefly to the attention of military surgeons. As army medical officers are expected to be competent in a variety of branches of medical practice, among which otology and laryngology have now increased in importance, this book should be popular in all English-speaking countries, as it presents the subjects from the rather different point of view of military practice. There is an account of all the ordinary examinations, treatments, and operations likely to be encountered in practice amongst soldiers and their families, but a few points demand criticism. The arrangement of the book upon a symptomatic rather than a pathological basis will fail to satisfy many readers. The author states that a chronic discharge from the ear is indicative of neglect or faulty treatment of an acute inflammation of the middle ear. This opinion no longer holds good for many cases in which otorrhoea is associated with cholesteatoma. There are also many instances of loose writing, though the meaning is usually clear. The following is an example: "The indications for surgery in chronic suppuration of the ear are less clearly defined and more difficult to interpret than acute otitis media and mastoiditis." A more serious criticism relates to the use, advocated by the author, of pyramidon as a substitute for aspirin. Atophan in the form of arcanol is also recommended without warning against the danger of using this drug. On the whole the advice given in the management and treatment of patients is sound, and the author shows wisdom and caution in many points likely to arise, and his book can be recommended as a useful guide both in civil and in military practice.

Notes on Books

A total of 188 cases occurring in Sweden, Norway, and Denmark form the basis of A. GREVILLIUS'S monograph on malignant tumours of the testis, *Über Maligne Hodengeschwülste*, published by Appelbergs of Uppsala. Among important points which emerge from their analysis are the diagnostic and prognostic value of detecting sex hormones in the urine, the prognosis and degree of radio-sensitivity of different types of tumours, and the relative values of extirpation and of irradiation in treatment. There are good photomicrographs of many representative tumours, a brief statement in tabular form of the main features and clinical course of all the cases, and a useful bibliography.

In *A Natural Golfer* (London: Thomas Murby, 10s. net) Dr. J. FORREST returns to the self-imposed and formidable task of converting the artificial golfer into a natural one. Once again the secrets of the successful golfer are traced to wrist action and fittingly caught and photographed. Most golfers live in the hope that the next round is going to be better than the last, and will open this book with the secret hope that there may be "something in it." What that is may best be seen in the lovely photographs of Jack Hobbs on page 83.

MEDICAL WORK OF THE MINISTRY OF PENSIONS

From the medical standpoint the most important practical task of the Ministry of Pensions is the provision of treatment. Few of those engaged in the work to-day can recall the extent of the institutional organization which has been in existence, and many of the institutions in former use are now mere names unassociated with any particular memory.

Institutional Accommodation since 1918

While the Ministry opened certain hospitals itself, for the most part the accommodation was taken over from the Services and for some time continued to be held under D.O.R.A. or under private arrangement with the owners of the property. Some were purely temporary huddled hospitals, others Poor Law institutions, mental hospitals, and private houses converted to general or special hospital use. The first hospital was acquired in February, 1918, but the acquisition of further hospitals during the continuance of the war was slow. By March, 1919, however, arrangements were in full swing for the transfer or setting up of hospital accommodation considered to be necessary to meet the problem with which the Ministry was faced, and by March, 1920, over 10,000 beds had been acquired, spread over forty-eight institutions controlled by the Ministry and used solely for the treatment of disabled ex-Service officers and men. The peak of the Ministry's institutional work was reached in 1921 when over 14,000 beds were acquired, not to deal with the whole of the Ministry's liability for in-patient treatment but only such part as needed special provision and in the main was not or could not be provided by existing civil institutions. Ministry accommodation provided less than 50 per cent. of what was required, for at the end of the year 1920-1 there were still nearly 31,000 pensioners in hospital, while during the year it had been necessary to treat 135,000 cases.

Altogether the Ministry has occupied at one time and another eighty-three hospitals and six convalescent centres, and the nine hospitals which still survive are for the most part replacements of the original war hospitals which had been closed because they had become unsuitable or were required for their original peace-time use.

The Position To-day

By March 31, 1938, the bed strength in Ministry hospitals had been reduced to 1,598, while the total number treated during the twelve months preceding that date had fallen to just over 6,000. There are, however, certain signs which suggest that a stage is being approached where reductions in the numbers requiring treatment characteristic of earlier years can no longer be looked for, and that indeed increases must be expected in some directions. Thus it is found that the total number treated during the year 1937-8 rose by 17, whereas there was a drop of 401 in the preceding year. Never before has the number in hospitals in succeeding winters approximated that of the previous year, but the number in the winter of 1937-8 was in fact in excess of that twelve months earlier.

With advancing years the disabilities, whether they be wounds or diseases, are becoming more in evidence and more and more resistant to treatment, thereby necessitating longer and more frequently repeated institutional care. Admissions themselves were in excess of the previous year and included no fewer than 473 cases for investiga-

tion, the difficulties and complexities of which are increasing as the war years recede into the background of the medical history.

Deaths in Ministry Hospitals

In spite of the greatly increased number of gravely ill pensioners the death rate in Ministry hospitals tends to diminish and is now only 2.2 per cent. of those admitted. Of the 138 deaths in Ministry hospitals during the year it is of interest to note that respiratory diseases (32.6 per cent.), diseases of the cardiovascular system (23.2), affections of the renal system (12.3), and malignant disease (8) account for 76 per cent. of the total. It is not until we come to septicaemia (6.5 per cent.) that any condition is approached which appears to be the late effect of a battle casualty apart from those respiratory diseases that have been accepted as being the result of poison gas. Investigation as to what extent direct enemy action during the great war was still responsible for deaths among ex-Service men reveals that battle casualties accounted for only 16.5 per cent. in 1936-7, though this increased to 24 per cent. in the year ending March 31, 1938.

Provision of Treatment

As heretofore treatment is provided by the Ministry itself only when facilities which are otherwise provided from public funds are not available, and the treatment of insane and tuberculous pensioners (other ranks) continues normally to be provided by the respective local authorities.

Of the total number of 13,659 other ranks provided with in-patient treatment during the year 6,133 received it in Ministry hospitals, 5,771 in mental hospitals, and 763 in sanatoria. The remaining 992 were those treated in civil hospitals, some of which are reserved exclusively for ex-Service patients, others only in part, the remainder being ordinary civil hospitals. Out of a total of 2,746 pensioners provided with out-patient treatment just over 2,000 were treated at Ministry clinics, the bulk of the work being undertaken at the special surgical clinics.

The supply of new artificial limbs reached over 4,000 and over 33,000 were repaired, while the death of 355 amputees was in part offset by 101 fresh amputations, of which 59 were primary and 42 re-amputations. The number of appliances provided by the Ministry continues to increase, and a substantial addition in the number of invalid chairs and tricycles supplied during the past year must be regarded as to some extent due to advancing years and progressive deterioration of the disabilities.

The amount of work done in the wards of each Ministry hospital is reflected in the activities of its ancillary services. All Ministry hospitals make use of the Central Laboratory at Roehampton for reports on their pathological specimens, 15,706 of which were dealt with during the year 1937-8, involving over 27,000 separate investigations. This is an increase of more than 2,000 over the figure for the previous year and affords an interesting indication of the growing need for investigation.

War's Aftermath

It will be seen from this brief review, which touches only one aspect of the Ministry's activities, how much has been done and still remains to do for those disabled by a conflict that raged twenty years ago. The record stands as an impressive warning of the prolonged suffering that follows in the train of modern warfare and as an appeal to the humanity of all nations to prevent such a calamity in the future.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY NOVEMBER 19 1938

THE PITUITARY AND DIABETES

Ten years ago it was supposed that diabetes was due simply to a deficient secretion of insulin. In 1930 Houssay¹ and his collaborators observed that the symptoms of diabetes in depancreatized dogs were relieved by hypophysectomy, and subsequently that injection of crude extracts of anterior pituitary material into such "Houssay dogs" (hypophysectomized-depancreatized animals) caused diabetic symptoms to develop. Since that time the influence of the anterior pituitary on carbohydrate metabolism has been the subject of intensive study. Much of this work has been undertaken in this country by F. G. Young, who has recently reviewed the present state of knowledge.^{2,3} Before Houssay's classical observations it was known that the glycogen stores of the liver were derived not only from carbohydrate but also from protein and fat, and that the mobilization of this glycogen to supply a constant blood-sugar level was controlled by a number of factors of which adrenaline was one of the most important. Adrenaline was also responsible for helping to convert tissue glycogen to lactic acid. The hypoglycaemic action of insulin was due to its powers of preventing the formation of glycogen in the liver, to its antagonistic effect on the mobilizing function of adrenaline, and to its facilitating the conversion of blood sugar to tissue glycogen. If the supplies of carbohydrate were adequate the conversion of fat to glycogen was prevented by insulin. In the process of this conversion there was a tendency to liberation of ketone bodies, so that insulin in the presence of glucose diminished the tendency to ketosis.

F. G. Young⁴ has shown that administration of crude anterior pituitary extracts to normal dogs gives rise to hyperglycaemia, glycosuria, and ketonuria. With small constant doses this diabetogenic effect tends to disappear, but can be made to reappear if the daily dose is increased, and if large doses are given the dogs are rendered permanently diabetic.⁵ These animals, however, can survive indefinitely without insulin treatment and can readily manufacture sugar from protein,⁶ so that, provided they are supplied with a high protein diet, their body weight is maintained or even increased. It

appears that this diabetogenic effect is due not to inhibition of secretion of insulin but to the raising of the threshold of sensitivity to it.⁷ Young⁸ found that extracts of the lactogenic hormone of the anterior pituitary, prolactin, possess this diabetogenic activity, though he⁹ subsequently demonstrated that the "glycotropic factor" is a contaminant of, but not identical with, prolactin. Although crude extracts of the anterior pituitary are "diabetogenic" neither prolactin nor the glycotropic factor will raise the blood-sugar level in intact animals, though they will provoke glycosuria in "Houssay dogs."¹⁰ Furthermore, neither prolactin nor the glycotropic factor will induce ketonuria either in the intact¹¹ or in the "Houssay" animal.¹⁰ So at least three different factors would appear to be required to produce the "diabetogenic" effect in the intact animal: the glycotropic factor, the ketogenic factor, and a factor responsible for inducing glycosuria in the intact animal. Further information as to the mode of action of the glycotropic factor is provided by the observations of Himsworth and Scott¹² that this substance is equally active in adrenalectomized animals, and that its effect therefore is not brought about by increasing the glycogenolytic power of adrenaline. In a histological study of the pancreatic islets in diabetic animals Richardson and Young¹³ observed that, whereas in dogs rendered permanently diabetic there is evidence of degeneration of the Langerhans tissue, in rats receiving crude extracts of anterior pituitary there is an increase in the amount of islet tissue, and in dogs receiving small daily doses active mitosis of the cells is found. This is of significance in view of the observation that such animals tend to become resistant to the diabetogenic effect of small doses, and supports the evidence for the existence of a "pancreatropic" factor of the anterior lobe. Yet another aspect of this pituitary activity is the self-limiting mechanism which appears to be a function of all anterior pituitary factors. Young¹⁴ has shown that by continuous treatment of monkeys with glycotropic substance it is possible to develop an "anti-prolactin" in the serum, though this antigenic substance does not appear to be consistently anti-glycotropic.

The story is by no means complete, but enough has been told to show that the normal animal, and presumably the normal human being, like the "Houssay dog" lives "precariously balanced between hypoglycaemia and diabetes," and that this balance depends on the efficient interaction of the anterior pituitary and the pancreas. It is still too early to apply these discoveries clinically, but we

¹ *Endocrinology*, 1931, 15, 511.² *Lancet*, 1936, 2, 237, 297.³ *Proc. roy. Soc. Med.*, 1938, 31, 1305.⁴ *Biochem. J.*, 1938, 32, 513.⁵ Young, F. G. *J. Physiol.*, 1938, 92, 15P.⁶ Marks, H. may look forward confidently to a third milestone in the history of the treatment of diabetes which may prove to be not less important than the discovery of insulin by Banting and Best or the introduction by Hagedorn and Scott of the protamine-zinc-insulin compound.

RAW AND PASTEURIZED MILK

Two reports have already been issued describing work carried out under the supervision of the Milk Nutrition Committee on the comparative nutritive value of raw and commercially pasteurized milk. The first dealt with observations on rats, the second on school children. A third report¹ is now published dealing with experiments on calves carried out at the National Institute for Research in Dairying, Reading, and at the Rowett Research Institute, Aberdeen. At Reading sixteen pairs of bull calves from tubercle-free herds were compared. One animal in each pair was fed on raw and the other on pasteurized milk from the same source. The milk was given in proportion to the weight of the animals. A hay supplement was included after eight weeks and a meal supplement after seventeen weeks. The experiment terminated after twenty-six weeks. In assessing the results five pairs of calves were omitted on the ground that three calves on raw milk died of pneumonia, one calf on raw milk was ill, and one calf on pasteurized milk had intestinal obstruction. The average weight of the remaining eleven pairs was 453.9 lb. in the raw group and 454.36 lb. in the pasteurized. Body measurements showed a slight but insignificant advantage in favour of the animals on raw milk; but, since the difficulties of obtaining uniform measurements in calves are said to be great, little weight can be attached to this difference. Examination of the raw milk showed that 30 per cent. of samples contained tubercle bacilli, in spite of the fact that it came mainly from accredited herds. None of the pasteurized samples was found to be infected. Tuberculin tests made towards the end of the experiment showed that eight out of the eleven calves on raw milk and one out of the eleven on pasteurized milk reacted positively.

At Aberdeen two experiments were carried out on the same general lines as at Reading. In the first experiment six heifer and ten bull calves were included in each group. Milk was fed according to appetite up to four months and then limited to 20 lb. per head per day. Hay was not given, but oat straw was fed freely throughout. Meal was added after four months. In the second experi-

ment ten pairs of bull calves were observed, milk being limited to 15 lb. daily, and meal added as soon as the calves would eat it. The milk supplied was the same in both experiments. Of the raw milk 74 per cent. of samples contained tubercle bacilli and 74 per cent. *Br. abortus*; of the pasteurized milk 7 per cent. of samples contained tubercle bacilli and 5 per cent. *Br. abortus*, though it is stated that the phosphatase test was uniformly negative. In the first experiment, omitting two calves that died in the raw milk group and one in the pasteurized, the average weight at 183 days of the animals fed on raw milk was 417.9 lb. and of the animals fed on pasteurized milk 402 lb. This difference cannot be regarded seriously, since throughout the experiment the growth curves of the two groups of animals were frequently crossing each other, and it so happened that at the time the experiment came to an end the animals on raw milk were in the ascendant. In the second experiment the average weight of the animals at the end of 187 days was 379.6 lb. in the raw group and 352.2 lb. in the pasteurized. In neither experiment was the difference in weight statistically significant. In the first experiment four calves in the raw group and three in the pasteurized reacted to tuberculin; in the second experiment the numbers were four and one respectively.

There are several different ways of carrying out experiments of this sort, and the answer obtained necessarily depends on the type of procedure adopted. Wilson, Minett, and Carling at Peppard endeavoured to make a pure comparison of the nutritive value of raw and pasteurized milk. For this reason they used calves from a healthy herd and fed them with milk that was free from both the tubercle bacillus and *Br. abortus*. As a result none of their animals became infected, and the results were not vitiated in any way by disease. Wilkie, Edwards, Fowler, and Wright at the Hannah Dairy Research Institute wanted to compare the general effect of raw and commercially pasteurized milk. For this reason they used animals from tuberculosis-free herds, fed them on ordinary raw and pasteurized milk, and kept them under completely separate housing conditions. The result was that twenty-four out of the thirty-six animals on raw milk became infected with tuberculosis and not one of the animals on pasteurized milk. In both these experiments, it may be noted, the average gain in weight of the animals was either equal or slightly higher in the pasteurized than in the raw group. The Reading and Aberdeen workers seem to have fallen between two stools. Some of their animals came from tuberculin-tested herds and others did not. Ordinary raw and pasteurized milk were given, but the animals were all housed together. It is not surprising, therefore,

to frustration. The attack by biopsy is a bold method and is designed to avoid the disturbances caused by agonal and post-mortem changes. Nevertheless, it itself is not entirely free from the possibility of criticism. Scholz² has said that small portions of brain tissue, obtained fresh and preferably by biopsy, are in a high degree susceptible to artefacts produced by the hardening process. Dr. Penfield, however, has stated that he has never seen marked swelling in the oligodendroglia cells in bioptic material without there being some disturbance in the consciousness of the person from whom the tissue came. It is very much a matter of debate what significance, if any, can be attached to swelling of the oligodendroglia. It is, as a rule, considered to be an acute change and not one that can persist uninterruptedly for a prolonged period of time. Examination by biopsy is well worth a trial where facilities are available. There are, however, few English clinics which would use such a measure when operation was not on other grounds advisable. With further experience the special advantages and disadvantages of the method will come to be better known. Confirmation of these results will be required before a solid basis for further work on these lines is possible. Even then knowledge may be but little advanced, and such pathological findings may show themselves to be concurrent changes and not of aetiological significance. Much excellent biochemical work has succeeded only in reaching such a paltry conclusion.

PATHOLOGY OF RETINITIS PIGMENTOSA

The very name "retinitis pigmentosa" is a hybrid of fallacious pathology and doubtful physiology. Whatever the nature of the lesion it is not an inflammation of the retina, and that the pigmentary disturbances are not an essential feature of the process is shown by the existence of the subvariety of retinitis pigmentosa sine pigmento. The experimental work of Wagenmann, who studied the effect of cutting the short posterior ciliary arteries in rabbits, tended to implicate the choroidal circulation as the seat of the primary lesion, but the hereditary character of the affection and some histological features point to the retina rather than the choroid. Wagenmann's work, which was accepted as valid for many years, has recently been challenged,³ and opinion as to whether the primary lesion is one of the retina or of the choroid is still divided. The histological features of retinitis pigmentosa have led equally weighty authorities to support both views. General studies on the whole have been unhelpful until the recent revival of interest in the Laurence-Biedl syndrome with its widespread disturbances. Zondek,⁴ in particular, and many Italian writers have insisted on the endocrine basis of the disease; but the evidence is far from conclusive, and especially so in the case of attempts to single out a pituitary disturbance as the essential feature. Considerable interest therefore attaches to the work of E. C. Dax,⁵ who has

shown that the blood and urine of twenty patients with retinitis pigmentosa contain a substance which on injection into frogs disperses the melanosomes of the skin. The same effect is produced by the urine of patients with pituitary abnormalities or by urine excreted at times when the gland is subjected to physiological stress, as in menstruation. This wider view of retinitis pigmentosa, however, still leaves unsolved the problem as to the primary seat of the affection, though it tends to support the belief in an essentially retinal origin. The conception of retinal abiotrophy,⁶ though criticized as an escape into mere terminology, has by now yielded sufficiently valuable results in the discrimination of a large group of degenerative lesions to gain a new meaning. That retinitis pigmentosa is fundamentally a slow and premature death of the fully organized retina is further borne out by the investigation of this condition in a batch of rats undertaken by Bourne, Campbell, and Tansley.⁷ The material at their disposal enabled them to make something like an experimental study of the lesion in the retina at different stages, and their evidence is distinctly against the choroid as the primary source. It is not easy to see just how far a pituitary disturbance fits into such a picture. Assuming that it can be proved that such disturbances are invariably present in retinitis pigmentosa the question still remains as to whether the pituitary disorder is the primary factor or whether it is merely an associated condition arising out of the same underlying cause. Much more confirmatory evidence is needed before it can be accepted that retinitis pigmentosa is a pituitary dysfunction and nothing more. This view will also have to be harmonized with the evidence available on the rather ill-understood role of vitamin disturbances in the affection, as also with the pigmentary degeneration of the retina which can be experimentally induced by sodium iodate.

TROPICAL MACROCYTIC ANAEMIA

It seems clear that one of the fundamental causal factors in tropical macrocytic anaemia is a dietetic deficiency and that similar anaemias in varying degree are widespread. Hamilton Fairley and his colleagues⁸ have therefore suggested that the condition should be called nutritional macrocytic anaemia, and as a result of their observations in Macedonia they divide this into two varieties: a non-haemolytic and a haemolytic. The first variety is rare in Macedonia and seems to arise from uncomplicated dietary deficiency, whereas the second is common and appears to be due to dietary deficiency complicated by chronic malaria. Malaria exerts its action not directly on the red cell but through the increased phagocytosis of abnormal red cells derived from a pathological bone marrow by a reticulo-endothelial system activated and hypertrophied, it is thought, as a result of chronic malarial infection. A remarkable feature of these cases was the resistance to treatment. Massive doses of marmite (60 grammes

or more daily) or liver extract (6 to 8 c.cm. campolon daily) were required to produce maximal reticulocytosis and blood regeneration; and even so the blood counts increased slowly. As the reticulocyte response was generally adequate it seemed that blood regeneration, even if adequately initiated, could not be maintained, or, in accordance with the general theory of the authors, though satisfactory blood regeneration was taking place the new blood was being destroyed by the hypertrophied reticulo-endothelial system. Another interesting question is the relation of tropical macrocytic anaemia to pernicious anaemia. From observations both on the experimental deficiency anaemia of monkeys (the supposed animal counterpart of human tropical macrocytic anaemia) and on the human disease itself, Wills and Evans⁹ claim to have shown that, whereas crude liver extracts are effective, the highly purified extracts so potent in pernicious anaemia are relatively inert, even in enormous doses. They state that in tropical macrocytic anaemia anahaemin, although the doses used were very high, produced no clinical improvement, no reticulocyte crisis, and no appreciable rise in the red cell count, and that similar results were obtained with examen; Napier and his colleagues¹⁰ support this opinion respecting anahaemin. These observations would suggest that uncomplicated tropical macrocytic anaemia is due to a deficiency in the diet of some factor other than Castle's extrinsic factor. The precise nature of this new factor, present in crude liver and autolysed yeast extracts, has not yet been demonstrated, though it does not appear to be vitamin B₁, B₂, lactoflavin, or nicotinic acid. However, until its identification and isolation are completed and its relation to other haematopoietic factors is determined, all cases of tropical macrocytic anaemia should be treated by the cruder liver extracts or by marmite; and, furthermore, the effect of any secondary haemolytic factor, such as chronic malaria, on the dosage required to produce a therapeutic response must be kept in mind.

PASTEUR INSTITUTE, 1888-1938

The Pasteur Institute in Paris, which celebrated its fiftieth anniversary this week, was opened on November 14, 1888, by the President of the French Republic in the presence of a distinguished gathering in the large library. It may be of interest to record one or two incidents that took place on this historic occasion. Dr. Grancher, who spoke after the proceedings had been opened by a brief speech from M. Bertrand, the secretary of the Academy of Science, inveighed against the opponents of the "Pasteurian method," and favourably contrasted the action taken by the Committee of Investigation appointed by the English Government. Dr. Grancher recorded that since the middle of 1885, when the first two patients were inoculated against rabies, 5,384 persons had passed through the laboratories at Rue d'Ulm and Rue Vauquelin. At that time twenty laboratories had been established for preventive inoculation: seven in Russia, five in Italy, and one each in Rumania, Austria, Brazil, Cuba, and the Argentine Republic—one was shortly to be opened at Chicago

and one in Malta. After Dr. Grancher had spoken M. Christophle, the treasurer of the Fund, reported that the subscriptions, including handsome donations from the Czar of Russia and the Sultan, amounted to over £100,000, three-fifths of which had been spent in building and equipping the Institute, leaving only £40,000 as capital for an endowment fund. The Government had been making a grant of £5,000 a year, but Pasteur and his committee hoped to obtain further private subscriptions which would render the Institute independent of the State. When the time came for Pasteur to speak he was so overcome that the speech which he had prepared had to be read by his son. It is worth recalling that Joseph Meister, at present lodgekeeper of the Institute, was the first person to be treated by Pasteur's method: this was on July 6, 1885, when at the age of 9 years he was bitten by a mad dog.

BRITISH HEART JOURNAL

At the beginning of next year the British Medical Association will increase its services to medical science by publishing quarterly a special journal devoted to diseases of the heart and of the circulation, under the title *British Heart Journal*. This journal, which is being published at the request of the Cardiac Society of Great Britain and Ireland, will be jointly edited by Dr. Maurice Campbell and Dr. Evan Bedford, assisted by an editorial board appointed by the Cardiac Society. Diseases of the heart and the circulatory system form the first of the principal certified causes of death at all ages in this country, and it is therefore a matter of surprise that such a journal is not already in existence in view of the gravity of the conditions which will form the subject-matter of this new publishing venture. We do not, of course, forget *Heart*, which for many years was edited by Sir Thomas Lewis and held a unique place in the medical literature of the world—a position still maintained with change of title to *Clinical Science*, but happily without any change of editorial guidance. The research work in experimental medicine that is carried out under the leadership of Sir Thomas Lewis, the reports of which appear in his journal, are of supreme importance to medicine, and represent a field of activity that probably will only be incidentally surveyed in the *British Heart Journal*. In the new periodical one may expect to find work more concerned with the everyday diagnosis and treatment of patients, and so of immediate value to the practising physician. Its obvious appeal will, of course, be to the specialist in heart disease or "cardiologist," both in this country and in others, but we would, too, strongly commend it to all physicians to whom the stethoscope of Laennec has become the badge of their tribe. In shape and form it will be similar to the other two specialist journals published by the B.M.A., and it will be priced at 25s. a volume of four numbers.

We regret to announce the death, on November 14, of Patrick Watson-Williams, M.D., consulting surgeon in charge of the Ear, Nose, and Throat Department, Bristol Royal Infirmary. We hope to publish a memoir next week.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

INNOCENT TUMOURS OF THE BREAST

BY

W. SAMPSON HANDLEY, M.S., F.R.C.S.

Unless the diagnosis is certain and the tumour of very moderate size, the removal of a benign swelling of the breast should not be undertaken as an exercise in minor surgery. While in some cases, as in the mobile fibro-adenoma of the young woman in her twenties, the lump may be unquestionably innocent, in a woman over 40 a clinically similar lump may prove to be a mobile carci-

Owing to the close relation of the great pectoral muscle to the breast early movement of the arm is very undesirable.

The dressing applied should maintain elastic pressure upon the field of operation, and, except for the smallest operations, a many-tailed bandage is best, as it ensures uniform support for the whole breast.

Removal of an Encapsuled Fibro-adenoma

A direct approach to the tumour is usually best by an incision radiating from the nipple so as to avoid division of main ducts and situated over the most prominent part of the swelling. The tumour should be steadied and made prominent by fixing it between the thumb and index

FIG. 1.—The method of approach to the tumour

noma, for which an immediate radical operation is desirable. In some cases an immediate frozen section by a pathologist in attendance may be necessary to settle the question, and if malignancy is reported it is desirable, though not absolutely essential, that immediate radical operation should follow. If this is not possible the wound should be immediately sewn up and the patient sent to a fully equipped hospital. In any case where cancer is suspected the scope of the exploratory operation should be as restricted as possible, and the incision should be one which will not prejudice a subsequent radical procedure—that is to say, the lump should be approached by a small incision made directly over it, and not by an indirect or marginal incision. It is a safe rule that no case in which a carcinoma may be present should be submitted to exploration unless the surgeon's experience and environment justify, if necessary, an immediate major intervention.

It is a mistake to minimize to the patient beforehand the importance of even a small operation, for this will make it more difficult to control her during convalescence. Even a small wound takes a week to heal firmly. In a vascular organ such as the breast rest for a week with the arm in a sling should usually be insisted on. Early movement is likely to produce a troublesome haematoma, which will delay recovery and may possibly require evacuation.

FIG. 2.—Showing the incision down to the tumour and through its capsule.

finger of the left hand (Fig. 1). A firm cut is made right down to the tumour and through its capsule (Fig. 2). The latter is an essential point, for the plane of easy enucleation is not between the tumour and its surroundings but between the capsule of the swelling and the tumour substance itself. With a blunt instrument—a blunt dissector, a closed artery forceps, or the gloved finger—the enucleation is now carried out, as a rule without difficulty (Fig. 3). The cavity is then inspected to see that no lobules of the tumour have been left behind. Some surgeons advise that the capsule should now be separately excised, but I think this is unnecessary. The cavity is examined for bleeding points, which should either be carefully ligatured or else underrun with a fine semicircular needle carrying a ligature, which is then tied over the bleeding point. The latter is the safer plan. With a similar needle the cavity left should be obliterated by approximating its sides. The needle takes a grip first of one lateral wall of the cavity and then of the corresponding point on the opposite wall. The ligature is now tied. Two or three such stitches may be necessary (Fig. 4). A narrow strip of corrugated rubber may be put in as a drain for twenty-four hours, but should not be left longer. It only remains to insert the skin sutures. Double horsehair, which is elastic and non-absorbent, leaves little mark if not left in too long,

or thin silkworm-gut or clips may be preferred. Special care must be taken that the skin edges are not inverted and are accurately coapted. If an invisible scar is hoped for the stitches must be removed early—say on the fourth or fifth day. After their removal it is well to apply a single layer of gauze over the wound and to paint it with collodion. This will prevent gaping of the incision.

FIG. 3.—The method of enucleation.

FIG. 4.—Obliterating the cavity.

Unencapsuled Fibro-adenoma

Certain fibro-adenomas have no capsule and cannot be enucleated. They can only be removed by cutting round the tumour, preferably with curved scissors, where it merges into the surrounding breast. If a fibro-adenoma proves to be non-enucleable a suspicion of carcinoma should be aroused.

Gaillard-Thomas Method

In cases in which it is desirable to avoid a scar over the surface of the breast access to the outer position of the organ can be obtained from the posterior surface by the Gaillard-Thomas marginal incision. (Fig. 5). The operation, however, may be attended by free bleeding, and lies

on the edge of the domain of minor surgery. At least a dozen artery forceps should be available. Usually the incision begins in the axilla just under cover of the lower

FIG. 5.—The Gaillard-Thomas marginal incision.

FIG. 6.—The cavity as it appears after enucleation of the tumour.

FIG. 7.—The skin sutures.

edge of the great pectoral muscle, and follows downwards the curved outline of the breast for the requisite distance according to the freedom of access required. If the tumour is near the lower edge of the breast the incision will follow the submammary sulcus. The incision is deepened down to but not through the deep fascia, and then, partly by blunt dissection, the breast is raised from the fascia until the tumour can be felt through its posterior surface, which is turned over until the tumour presents. An incision is now made through the posterior surface of the breast, the tumour exposed and enucleated, and the cavity obliterated as already described (Fig. 6). The breast is turned back into position and a drainage-tube inserted after careful haemostasis. Only few skin sutures are necessary (Fig. 7), and healing is usually rapid and satisfactory.

The weakness of the Gaillard-Thomas method is that if the tumour proves after all to be malignant a subsequent satisfactory radical operation is made difficult or is impossible. This incision should not be used if there is any doubt as to the diagnosis.

Pathological Examination Essential

Cases are on record in which, after the removal of a fibro-adenoma, carcinoma has appeared beneath the scar within a few months. The supposed fibro-adenoma, if microscopically examined, would almost certainly have proved to be a carcinoma. Remembering such facts, no conscientious surgeon will remove a portion of tissue from the breast without sending it for microscopical examination. To this rule there should be no exception, for carcinoma has been found in the interior of an apparently undoubted fibro-adenoma.

Doubtful Breast Swellings

The condition which most often arouses suspicion of early carcinoma is chronic mastitis, especially of the cystic variety. Chronic mastitis has already been considered.* This condition affects the breast by lobes, attacking certain lobes and often sparing others. The upper and outer quadrant is the most common site, as for carcinoma. Chronic mastitis, especially of the cystic variety, is a pre-cancerous condition, though it may be many years before the change to cancer supervenes, and that change may never occur. The swellings of chronic mastitis are vague, mobile, finely granular, sector-shaped, and free from adhesion to skin or fascia. The lymphatic glands may be enlarged and tender, but they are elastic and not hard. Swelling and tenderness of the breast are maximal just before the period starts, and rapidly subside once it has begun.

In its typical form, and especially under the age of 40, mastitis is best dealt with by a short course of x rays to the breast, and the question of surgery will not arise. But in women who have reached the cancer age mastitic swellings should be examined every three months, even after x-ray treatment has been given.

A watch should be kept for certain danger signals which indicate the likelihood of early supervision of carcinoma. These are:

1. The appearance of multiple hard lumps, probably cysts or fibro-adenoma, in the mastitic area.

2. Deviation of the axis of the nipple on the affected side.—The normal nipple looks forwards, downwards, and outwards. Fibrous tissue occurring in the mastitic area tends to tilt the nipple in the direction of that area. Thus in mastitis of the upper and outer quadrant the nipple is likely to point forwards and outwards, not forwards, outwards, and downwards.

3. Duct retraction.—This sign must not be confused with retraction of the nipple. Upon the normal nipple there are fifteen to twenty openings, one for each lobe of the breast. If one of the lobes becomes fibrotic the contraction of the new fibrous tissue pulls upon the corresponding duct, which then appears as a tiny depression upon the surface of the nipple. Several such depressions may be present.

4. Elevation of the nipple may occur owing to the pull of mastitic fibrous tissue upon it as a whole.

5. Incipient adhesion of skin to the lump.

6. Incipient retraction of the whole nipple.

If some of these signs appear it may be necessary to advise the removal of a portion of the breast for microscopical examination, preferably by frozen section, with leave to proceed to a mastectomy if necessary.

* See article by Mr. Cecil Rowntree in the *Journal* of November 12.

Technique of Biopsy

Under proper aseptic conditions, with preparation of the skin by painting with iodine or mercurochrome, the suspected area is isolated by sterile towels and an incision about an inch long is made, mainly with the point of the knife, deeply into the breast tissue of the suspected area. The knife must go right through the subcutaneous fat and well into the breast tissue, which can be recognized by its more fibrous and resistant quality. The knife is not removed from the incision, but is used as a guide to introduce a pair of toothed dissecting forceps which seize one edge of the incision in the breast tissue deep down in the wound. Traction is now made on the forceps by lifting it up towards the surface and, without removing the knife, cutting is resumed. The knife is carried in a circle round the point of the forceps and the forceps comes away with a wedge-shaped piece of breast tissue. While this is being examined by the pathologist the cavity of the wound is washed out with 1 in 1,000 perchloride of mercury to coagulate any loose epithelial cells. A single deep suture may be inserted in the breast tissue to approximate the sides of the small cavity in it and to arrest haemorrhage. The wound is then closed.

It is a common fault to make too long an incision for a biopsy. The smaller the incision the better, provided an adequate piece of breast substance can be reached.

Though, as an ideal, immediate radical operation, with a fresh set of towels, instruments, gloves, and swabs, should follow a pathological report of carcinoma, this is not absolutely essential. If the services of a pathologist skilled in the interpretation of frozen sections are not to be had the biopsy specimen may be sent away to a laboratory for a paraffin section and further operation deferred until the report is received.

It was formerly believed on Bloodgood's authority that this more leisurely procedure would seriously increase the risks of recurrence if carcinoma were found to be present. There would appear to be no sufficient ground for this belief: nevertheless the interval between exploration and radical removal should not exceed a week.

THE PECKHAM HEALTH CENTRE

A Three-years Survey

The words "annual report" on the face of a document induce a sinking feeling in the heart of a reviewer, and generally the more worthy the organization the greater the depression. But about the Pioneer Health Centre at Peckham, whose "annual" report dealing with three years' work has now been issued, there is something indefinitely different. There is something different about the place itself, about the 600 to 1,000 people who go there every day, about the people in the gymnasium and the swimming pool. The visitor feels at once the atmosphere of social health. Moreover, many of these people suggest that they have got rid of some incubus, have found some new vitality, have released some hidden spring. Partly it is to be explained by the fact that they and their families have had a health overhaul, during which many of those minor maladies, not considered important enough to go to a doctor about, but nevertheless a drag on the wheels of life, have been discovered. They have been told what is wrong with them as a first step to getting it right. They are not treated at the Centre. The two medical directors and the medical consulting staff regard themselves as health advisers: their province is to examine and warn, but to concentrate on health and not on sickness, and not to duplicate the treatment services already provided. Up to

the middle of this year over 1,100 families had been examined, and in about 83 per cent. of the individuals something was found which needed treatment or correction—perhaps only a trivial ailment, or, it may be, the pre-clinical stage of some more serious malady, such as anaemia, hyperpiesis, or kidney disorder. One of the doctors remarked that among the women she examined when they first came to the Centre only about two were really fit, but on a second overhaul the vast majority had improved physically to a marked degree. The result is best described in the mechanical analogy adopted in the report itself—the feel of a motor car after decarbonization, adjustment of valves, setting of the jet, clearing the sump and renewing the oil, greasing the springs, taking up the slack in the steering gear, and adjusting the brakes. And, not least, refurbishing the coach-work!

That stimulating pamphlet *Biologists in Search of Material*, reviewed recently in these columns, was in effect the scientific report of the work of the Centre. But the Centre ranges over the whole field of living. It has given the opportunity to a section of London suburban population—perhaps the loneliest, least communal society in the country—to find social opportunities, companionship, and an outlet for unexpected faculties. For example, 157 married women, most of them middle-aged and astonished at their own achievement, have learned to swim. The value of it all is to be measured not in the pleasant glass-fronted building off a Peckham side street but in some hundreds of surrounding homes. The interest of the Centre in the family, which is its unit, begins while the family is still prospective. Young people about to marry are given a complete overhaul and a pre-marital consultation. When motherhood is expected particular attention is given to ensure as rich as possible an intra-uterine environment for the coming child. A number of women who had decided to have no more children are said to have changed their minds with the new outlook on maternal and family vitality which at the Centre no one can avoid, but have gone through their pregnancy not only with courage but with enjoyment. Provision for their confinement is arranged, if necessary, at local hospitals, and when they return to the Centre they are built up and instructed and looked after. The Centre is aiming at a membership of 2,000 families, but in the early years this remarkable sociological experiment depends on as much generous outside help as can be afforded to keep it going on an expenditure of £7,000 a year.

in the service of numerous voluntary nursing associations which are participating in the national service of salaried midwives.

The St. John's School in Poplar

It is therefore a satisfaction to record the establishment of a new post-certificate school in Poplar by the Nursing Sisters of St. John, which was opened by Sir George Newman on October 31 last. St. John's is a voluntary nursing organization which has been working in the east and south of London for exactly ninety years, and has, since the beginning of the present year, been responsible, under contract with the L.C.C., for the domiciliary midwifery of the whole of the Metropolitan Borough of Poplar. It is the intention of St. John's to reserve the whole of this area for the purpose of post-certificate training. Until a few months ago St. John's was associated with the General Lying-in Hospital in the conduct of the well-known Camberwell School for refresher courses, and it therefore brings considerable experience to the new centre.

St. John's Post-certificate School for Midwives is situated in the East India Dock Road, in the heart of a large industrial population. Study-bedrooms are provided for ten resident pupils; the services of well-known obstetricians as lecturers have been secured, and instruction will be given in the ante-natal clinics of three neighbouring hospitals through the most valuable co-operation of the L.C.C. and of the Royal College of St. Katharine. The large number of domiciliary cases which are available will allow of direct personal supervision of the pupils while actually engaged in the conduct of a confinement and in the management of the puerperium. This is a feature to which great importance is attached by St. John's, who hold that the full benefit of refresher courses cannot be obtained except through personal contact between teacher and pupil, and by supervision of the pupil when actually performing the duties of a midwife.

This effort of a voluntary organization to show how the new requirements of Parliament and the Central Midwives Board can best be met deserves recognition and welcome. Post-certificate teaching, organized in the manner proposed by the new school, should do much to maintain the efficiency of an important branch of the maternity service.

Reports of Societies

POST-CERTIFICATE TRAINING FOR MIDWIVES

One of the most useful provisions of the Midwives Act (1936) was that which gave the Central Midwives Board the power, not hitherto possessed by it, to require midwives whose names appeared on the Roll to take refresher courses from time to time. With welcome promptitude the Board proceeded to exercise these powers, and in April, 1938, it issued regulations requiring all midwives, with a few specified exceptions, as from January 1, 1939, to take a refresher course at intervals not exceeding seven years. It was laid down that these refresher courses should be of one month's duration, and should be residential, the student devoting the whole of her time to the work. The Act further provided that it should be an obligation of "every authority"—that is, every Local Supervising Authority—to provide, or to arrange for the provision of, these courses of instruction for the midwives practising in its area. At the time the Act of 1936 was passed facilities for the post-certificate training of practising midwives were non-existent over the greater part of the country, and even in London they were quite inadequate to provide for the large numbers who would become subject to the new requirements. Up to the present the Local Supervising Authorities have given little indication of an intention to establish centres at which post-certificate training could be given, either to their own salaried midwives or to those

RECTAL REACTIONS FOLLOWING IRRADIATION OF CERVIX

At a meeting of the North of England Obstetrical and Gynaecological Society in Manchester on October 14 Mr T. F. Todd (Manchester) read a paper on rectal ulceration following irradiation treatment of carcinoma of the cervix.

Mr. Todd discussed the incidence, pathology, and treatment of rectal reactions following irradiation. His material was studied at the Christie Hospital and Holt Radium Institute during the tenure of a research fellowship. Interest was aroused because these reactions were so often not recognized; several cases were referred after previous radium treatment elsewhere for further radiation of a reaction misdiagnosed as a rectal carcinoma. The literature was very scanty; such reactions had seldom been reported and nowhere was the pathology described.

Rectal reactions might be early, as acute proctitis, or late, as chronic ulcers with a distinct resemblance to rectal cancers; thirty-four chronic rectal reactions had been seen in approximately 800 treated cases. Morphologically chronic rectal reactions assumed one of two types. The first was a lesion restricted to the anterior rectal wall,

usually at the level of the cervix uteri, and forming a mobile ulcerated mass, some 3 to 5 cm. in diameter, resembling an operable carcinoma. The second consisted of a rectal ulceration similarly situated, but accompanied by gross perirectal induration, and the formation of a hard fixed mass enveloping the rectum, anchoring it to the sacrum, and resembling advanced inoperable cancer with an extensive extrarectal spread.

Symptoms and Aetiology

The onset was usually six to nine months after treatment. The symptoms included tenesmus, melaena, and often severe pain. The prognosis varied with the severity and type of the reaction. Spontaneous healing was the rule, but stenosis might occur and require colostomy. The aetiology of the condition was discussed in detail. Two factors were proven: that of local accidental over-dosage, as happened when the radium applicators slipped and were approximated to the rectum in the posterior fornix; and that of retroversion, which allowed the intra-uterine applicator to project against the rectum. Mr. Todd considered that the main aetiological factor was obliteration of the blood vessels in the posterior segment of the pelvis as a result of general high dosage. In one case coming to necropsy (the only one recorded) the rectal ulceration was shown to be due to mucosal necrosis. A perirectal mass was present and was composed of avascular fibrous tissue showing widespread vascular occlusion and histologically marked endarteritic changes.

The treatment of chronic reactions and their complications was described. Presacral neurectomy was done in four cases for the relief of pain and the acceleration of healing; the rationale of this operation was discussed. The incidence of rectal reactions could be minimized by preventing any misplacement of vaginal applicators, nursing patients in the prone position, and avoiding over-dosage. Presacral sympathectomy might be a prophylactic against massive perirectal fibrosis by reason of its vasodilator effect.

Unusual Cases

Professor DANIEL DOUGAL (Manchester) described a case of adrenal virilism. The patient was aged 49 and was referred to Professor Dougal by a radiological colleague who had been treating her for facial hirsuties. The undue growth of hair first appeared two months after the cessation of the menses. The patient's general condition was poor. The liver was enlarged. A laparotomy disclosed the presence of an adrenal tumour with multiple visceral metastases, and she died forty-eight hours later. The primary tumour proved to be a highly malignant tumour of the right suprarenal gland. The lungs were filled with secondary deposits, although these had been quite symptomless.

Professor MILES H. PHILLIPS (Sheffield) described a case of acute prolapse of the urethra. The condition occurred in a doctor's wife, aged 70 or more, who had had for many years a procidentia, for which she had refused all treatment other than a pessary. At no time had she had any urinary symptoms. She suddenly noticed a little blood on her clothes shortly after micturition. An examination disclosed a dusky-red elongated and almost insensitive swelling over one inch in length protruding from the vestibule, with the tell-tale orifice at its apex disclosing its true nature. The prolapse was easily dealt with by excision and suture, and she recovered completely. This was the fourth case of acute prolapse Professor Phillips had seen. He was surprised to find that no such case had been recorded in the *Transactions of the London Obstetrical Society* or in the *Proceedings of the Royal Society of Medicine* between 1859 and 1938. Possibly this was because the condition had not been thought worthy of record. On the other hand, this would be the thirteenth such case reported to the North of England Obstetrical and Gynaecological Society. It would appear that urethral prolapse occurred in either young children or old women. Excision always effected a cure, although the late Professor Leith Murray recorded four

cases which were successfully treated by digital replacement after the application of adrenaline.

Dr. MARY EVANS (Manchester) described a case of spontaneous rupture of the uterus. The patient had been delivered of her first child by craniotomy. She was well in her second pregnancy until the eighth month, when she came into labour prematurely, and after a labour of six hours was delivered normally of a living male child. Two hours after delivery she suddenly collapsed: the placenta was still retained and shoulder pain was very severe. Laparotomy disclosed a haemoperitoneum and a small rupture of the fundus. A total hysterectomy was performed, and showed an irregularly shaped placenta still *in situ* with a rupture of the uterine wall in the placental site.

Dr. J. W. BRIDE (Manchester) showed a specimen of a malignant melanoma of the left labium minus with secondary deposits in the inguinal glands. In view of the patient's age and poor condition radical treatment was impracticable, and all that could be done was a wide vulvectomy with removal of the larger glands. Dr. Bride then discussed a case of adenocarcinoma of the body of the uterus. The patient had had 110 mgm. of radium inserted for twenty-two hours four years ago on account of post-menopausal bleeding for which no cause could be found. The uterus was very much more enlarged than was usually the case in carcinoma corporis, and the cavity was very distended. Dr. Bride considered it unlikely that the growth was present four and a half years ago, and was of the opinion that the malignant change was probably due to the irritation of secretions retained in the uterus as a result of stenosis of the cervix following the radium treatment.

EXPERIMENTAL ASPECTS OF STREPTOCOCCAL INFECTION

At a meeting of the Aberdeen Medico-Chirurgical Society on November 3, with the president, Dr. H. E. SMITH, in the chair, Dr. JAMES HOWIE read a paper on some experimental aspects of streptococcal infection.

Dr. Howie emphasized that experimental streptococcal infections in laboratory animals, especially in mice, were of two varieties: either a trifling local lesion appeared, which rapidly resolved, or else the animal was overwhelmed by a septicaemic infection without any local tissue reaction at the point at which the organisms were injected. In man, on the other hand, while rapid invasion of the blood stream occurred in very virulent infections, this event was normally either averted or much delayed by a well-marked local tissue reaction. It was decided to attempt to produce in mice a streptococcal infection presenting the main characters of the human disease. To this end attempts were made to reduce the virulence for mice of a well-known laboratory organism—Aronson's streptococcus. This was a capsulated streptococcus of great virulence and stability; minute doses of culture, containing four or five organisms, regularly killed mice in twenty-four to forty-eight hours. This degree of virulence was associated with smooth colonies and with short-chained capsular forms.

Rough Variant of Aronson's Streptococcus

The organism was with difficulty induced to grow in media containing a concentration of 1 in 25,000 acriflavine. This concentration of the antiseptic was equal to forty times the maximum amount which normally permitted growth. Under these conditions the organism underwent rough variation and produced long-chained forms without capsules. In this condition it became entirely avirulent for mice: $\frac{1}{2}$ c.cm. of undiluted culture, containing 2,500 million organisms, was without effect. Virulence had been abolished rather than merely diminished. Kept under ordinary conditions this rough variant reverted gradually to the original form. In the phase of partial reversion its virulence was examined. Here it was found that the individual animal played the leading part

in determining the result; either the animal was overwhelmed by a streptococcal septicaemia or it remained indifferent to the injection of organisms. This method of approach to the problem, therefore, did not achieve the desired result, but it showed: (1) that antiseptics may abolish virulence in bacteria without actually killing them; and (2) the remarkable stability of virulence of Aronson's streptococcus—a biological phenomenon the reverse of that exhibited by ordinary strains of streptococci.

The next approach to the problem was made along the lines of work recently reported by Gay and his colleagues in America. Without discussing their experiments or conclusions in detail, it might be said that their belief was that macrophages were more important cells in tissue defence than were polymorphonuclear leucocytes. Workers in this country—notably McLeod—had criticized their contentions on the ground that they were testing the resistance to infection not of the body as a whole but of an area of granulation tissue which was able mechanically to exclude invasive organisms. Using Gay's technique extensive macrophage infiltrations were produced in the abdominal walls, omental sacs, and peritoneal cavities of mice. Virulent streptococci isolated from human lesions were injected intraperitoneally into these mice and into an equal number of normal controls. All the controls died in from twenty-four to forty-eight hours with an overwhelming septicaemia. In about half the experimental animals the fatal issue was delayed for from three to five days, but it was never averted. In only two animals did "abscesses" form in the peritoneal cavity. On section these "abscesses" presented appearances which supported McLeod's view that there was merely mechanical obstruction to the invading agent and not an enhanced resistance in any true sense. It was evident that this approach to the problem would not yield the results desired and other methods were investigated.

Mechanism of Infection

One method which was in some ways successful, Dr. Howie continued, and which yielded results of interest, was by the production of areas of "sterile inflammation" by calcium chloride. Virulent streptococci isolated from human lesions were injected into the peritoneum in mice with "calcium chloride inflammation" of their abdominal walls. Eighteen normal controls were also injected. All the controls died in from twenty-four to forty-eight hours; six of the experimental animals survived, and the rest died at times varying from two to sixteen days after injection. The mechanism of infection was studied. Streptococci rapidly entered the blood from the peritoneal cavity. In twenty-four hours they had localized in large numbers at the site of "calcium chloride inflammation." Here they produced well-marked abscesses and areas of cellulitis almost identical with those found in human infection. Reinfection of the blood stream occurred before death, presumably from these abscesses. The lesions produced were, on an average, about 20 by 15 mm., compared with lesions of about 5 by 3 mm. produced by streptococci alone. These areas thus behaved as "fixation abscesses," and apparently saved the lives of one-third of the animals injected, besides delaying the progress of infection in the others.

Conclusions and Clinical Applications

From these experiments, Dr. Howie said that three conclusions might be drawn: (1) organisms in the blood might localize in areas of reacting tissue; (2) this occurrence might favour the host's chance of survival, as in the experiments quoted; or (3) on the other hand, it might determine a severe and even fatal infection. It was, of course, dangerous and controversial to apply these experimental conclusions to clinical practice, but two questions seemed to arise. First, why would surgeons in this country not investigate the fixation abscess as a therapeutic measure in pyogenic infections not responding

to other forms of treatment? There was need for such investigation. Many French authors wrote favourably of the method, but more exact data were required than were given in the literature. Secondly, it was now known that bacteraemia was commoner than was formerly believed. Therefore, was it not probable in many of the *Cl. welchii* infections following operation, or even subcutaneous injection, that it was the patient who infected himself? The nurse or the catgut was usually blamed. But these experiments showing how organisms localized in areas of tissue reaction suggested that a similar mechanism might operate in human cases.

Local News

ENGLAND AND WALES

Croydon Epidemic of Typhoid

In the introduction to his annual report for 1937 as medical officer of health for the county borough of Croydon, Dr. Oscar M. Holden makes the following reference to the local epidemic of enteric fever:

"The health record of the year was unfortunately marred by an outbreak of typhoid fever in parts of Croydon supplied by the high-level water supply. A full report on the outbreak will be made at a later date. This outbreak, though not so excessive as an outbreak in another southern town in 1936, obtained very great publicity. Upon representations made by a group of citizens, who formed the South Croydon Typhoid Outbreak Committee, the Minister of Health decided to hold a public inquiry into the causes giving rise to, and the steps taken to combat, the outbreak. This inquiry is the first of its kind to be held. It opened on December 6, when an adjournment was made until December 21, from which date it continued until January 12, 1938. The holding of so comprehensive an inquiry, for which much detailed information had to be compiled, and at which many criticisms had to be met and combated, during the actual course of a serious outbreak of epidemic disease, placed heavy additional burdens upon the department, already working at high pressure to deal with the outbreak. It says much for the energy and loyalty of the staff of the department that both burdens were shouldered successfully. The findings of the Commissioner are now too well known to need any reiteration, but it is justifiable to inquire, first, if the inquiry could have been held just as usefully after the outbreak had been dealt with; and, secondly, if the findings could not have been arrived at as efficiently and more expeditiously by methods of a less elaborate and costly nature. If this procedure is to form a precedent, then medical officers of health will in future, when called upon to tackle an outbreak of epidemic disease, also have to take steps to protect themselves at the public inquiry held therein."

Child Guidance Conference

A preliminary programme has now been issued for the fourth Biennial Child Guidance Inter-church Conference to be held on Friday, January 27, and Saturday, January 28, 1939, at British Medical Association House, Tavistock Square, London, W.C. This conference is for representatives and professional members of staffs of child guidance clinics in Great Britain. On January 27, at 10 a.m., the president, Lord Blanesburgh, will give an opening address in the Great Hall, followed by a session on "Treatment of Parents." In the afternoon there will be a public meeting on "Juvenile Delinquency" under the chairmanship of Lord Alness; members of the public may be admitted to this by ticket, price 2s. 6d. The conference dinner will take place at the Café Royal that evening. On January 28 there will be three concurrent morning sessions: one for psychiatrists in the Council Chamber to discuss personality deviations and the diagnosis of psychoses, one for administrative representatives in the Hastings Hall to discuss the findings of the Feversham

Report on the voluntary mental health services, and one for psychologists in Committee Room A to discuss the scope of the educational psychologist working in the schools. The afternoon session in the Great Hall will be devoted to a discussion on "Substitute Homes." Inquiries about the conference should be addressed to the Child Guidance Council, Woburn House, Upper Woburn Place, W.C.1.

Kettle Memorial Lecture

In May, 1937, an appeal was issued to friends and admirers of the late Professor E. H. Kettle, M.D., F.R.S., for subscriptions towards a memorial fund. More than £730 was received; this has been invested and a trust fund set up, with Professor J. H. Dible, Dr. W. E. Gye, Professor G. Hadfield, Professor W. D. Newcomb, and Colonel A. H. Proctor as trustees. It was decided that the best way of commemorating Professor Kettle would be by an annual lecture to be delivered in rotation in the medical schools with which he had been associated—namely, the British Postgraduate Medical School, St. Bartholomew's Hospital Medical College, the Welsh National School of Medicine, and St. Mary's Hospital Medical School. It was further decided that the choice of lecturers and arrangements for the lecture in any year should be made by the school at which the lecture would be delivered. The inaugural lecture will be given on Thursday, November 24, at 5 p.m., by Professor W. W. C. Topley, M.D., F.R.S., in the large theatre of the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., by courtesy of the Board of Management. It is entitled "The Place of Pathology among the Medical Sciences," and the chair will be taken by Sir John Caulcutt, K.C.M.G., chairman of the Governing Body of the British Postgraduate Medical School.

Correspondence

Estimation of Blood Vitamin B₁

SIR,—I have read the paper by Drs. Eirwyn N. Rowlands and John F. Wilkinson in the *Journal* of October 29 (p. 878) with interest because I have just submitted for publication a paper in which I conclude that Meiklejohn's modification of Schopfer's method does not give a quantitative estimate of the vitamin B₁ in blood.

Rowlands and Wilkinson state that they have established the fact that the test gives a fairly reliable method of estimating the vitamin B₁ in blood. They say: "The only factor other than vitamin B₁ that has been shown to affect the mould growth is the concentration of nitrogen in the medium; allowance can be made for this." I should be interested to know how this allowance can be made when blood is present, because I have had difficulty in eliminating the adjuvant action of sources of nitrogen in blood. In addition, the first part of this statement is open to criticism. First, substances other than vitamin B₁ and its disintegration products are known to act as growth factors for the fungus. Secondly, a host of substances are known to affect its growth; for instance, if the authors will add a pinch of chalk to their modified Schopfer's medium (which is in many respects a poor medium) they will obtain, I suspect, an increase of perhaps 50 per cent. in the growth produced by either 0.1 µg. or excess vitamin B₁. They state (perhaps following Meiklejohn) that addition of small amounts of vitamin B₁ to blood usually increases the growth by the expected amount. I should be interested to know how often this result has been obtained, because I found that in 150 1-ml. samples of blood from different cases addition of 0.1 µg. of vitamin B₁ produced an increase of 50 per cent. or more over the expected amount in 63 per cent. of cases; in fifty experiments addition of excess vitamin B₁ to 1 ml. of blood invariably produced a greater growth than in the control with

excess vitamin B₁ alone (the average increase being 78 per cent.). They also state (perhaps again following Meiklejohn) that samples of 1, 2, and 3 ml. of blood give values in the ratio 1:2:3. I have tested this upon 235 different samples of human blood and find that in 155 the 3 ml. value (expressed in µg. per 100 ml. blood) has been one or more µg. higher than the 1 ml. value; in twenty-two samples the growth with 3 ml. of blood was greater than that given by excess vitamin.

My own doubts about the reliability of the test have been expressed only verbally in the presence of both authors; they are no doubt justified in disregarding them. But there can be no justification for ignoring statements of other authors that are not in agreement with them. Williams, who first suggested the use of a micro-organism for the assay of vitamin B₁, has stated in connexion with *Phycomyces* that "the use of fungi in quantitative testing for vitamin B₁ in extracts appears hazardous in the extreme." Van Veen in a Dutch journal concluded that in testing impure extracts (including blood) by Schopfer's method "the results were far from reliable; in fact, that they were at times entirely unserviceable." Schopfer himself has stated that the best way to use the method is first to isolate the vitamin by adsorption on fullers' earth. These statements demand attention.

With great diffidence I communicated last June (see *Quart. J. Med.*, October, 1938, 7, 591) the results of estimations by a slightly modified method of the apparent vitamin B₁ in only 200 different cases. I found significantly low values in cases of "alcoholic" (three cases), gastrogenous, and nutritional polyneuritis; in some cases of idiopathic hypochromic anaemia; and in scurvy. I found normal values in pernicious anaemia with or without subacute combined degeneration of the cord. My results were not published in print because I had then done determinations on only twenty-six normal controls; these gave a mean of 11.5 µg. per 100 ml., and a statistical analysis showed that there is one chance in 100 of an observation falling below 7.7 or above 15.2. Although the authors have reached the same conclusion about different diseases from their total of forty-eight cases, it is not justified by the results they publish. On the basis of only eight normal controls they consider the normal range to be 6.5 to 16.5 µg. per 100 ml.; a statistical analysis of their data will show that there is one chance in twenty that a determination will fall below 0.94 or above 16.5. Not a single one of their determinations is significantly low when judged by these standards, and yet they regard 5.5 µg. per 100 ml. as "gross deficiency." This figure, 5.5, is scarcely different from their lowest normal, 6.5, since "the error of the test is apparently less than 10 per cent." Further, in Fig. 3 they show two "specimen normal curves" in which the blood figures, after the injection of vitamin B₁, rise before falling rapidly "to normal levels" within an hour; in one of these two normal curves the level starts at a little over 5 µg. per 100 ml. (about 5.2) and is back at the same figure in two hours. Surely a mistake has crept in, because if 5.5 is "gross deficiency," why is 5.2 regarded as a "normal level"?

There are other points that I should like to raise, but I have already taken up too much of your valuable space. I do wish to emphasize, however, that the results Drs. Rowlands and Wilkinson publish are statistically worthless.—I am, etc.,

Oxford, Oct. 29.

H. M. SINCLAIR.

Medical Research in England

SIR,—The Harveian Oration prompts me to make a few comments on the difficulties and necessity of maintaining research work in the teaching hospitals.

After spending some seven months in German hospitals and university clinics I came away, like most English visitors, impressed by the intensity of their tradition of investigation. Good work is continually being turned out by young men of no outstanding abilities, and this all in the day's routine. Sir Edward Mellanby has touched on the organization that makes this possible. Our own teaching hospitals have no such strong tradition

and their organization is the very opposite of what is desirable for this sort of work. They are chiefly concerned with the practice of medicine and the education of good doctors. In this they excel. But their organization makes research work (other than purely clinical investigation) extremely difficult. The staff are chosen in most cases for their ability as doctors. Those who are appointed because of the original work they have done often find their careers as investigators automatically ended. On the other hand the younger men who have time and a fixed salary too often produce nothing. They lack "directors." It is abundantly clear that they cannot be expected to hit on useful and workable investigations; at any rate, in the long run they do not. In Germany they are not expected to—they are told what to do and how to do it. In England the seniors may give verbal encouragement, but they cannot set an example, and in most cases they have never themselves had the experience necessary to give advice.

Outside the teaching hospitals there are other places much better suited for this type of work. There are, of course, the special research institutes created for the purpose. Presumably they are as suitable as they can be made. There are also the large county council hospital systems, which are built on a plan very similar to the German model. They are comparatively affluent. They have a permanent salaried staff which is interchangeable with any hospital within the group. The superintendent has enough control to unify and co-ordinate the work. As yet they have made no use of these possibilities, and for this there are many good reasons. For one thing they have still less tradition of research than the teaching hospitals. But the most important is that there are not enough men in England with the right technical training and above all with the right habit of thought to seize these opportunities. The frame of mind that can deal satisfactorily with sick people is quite different from that which contributes to the science of medicine. We cultivate chiefly the former and the Germans the latter. But they are both susceptible of cultivation, and since we need more men with a scientific bent we must turn once again to the places where these trends are determined.

It is clear that whatever research institutions one may design the staff must be recruited from the students and housemen in the teaching hospitals. At the moment we depend on some idealists and a few who fear the more boisterous competition of practice. These may be very good, but they are not enough. If the average capable man is to be attracted to this work he must see it going on around him as often as he now sees good medicine, and he must have the opportunity of imitating it in the same way. The difficulties and fascinations of their own investigations must become as much "shop" in the common-room as are their triumphs and failures in medicine. It is useless from this point of view to create centres at Hampstead and Mill Hill. Their very prestige and success increase their remoteness when the student cannot see the first steps that lead there. Investigation, therefore, must be brought into the daily routine of the young man and held there despite all discouragement.

This organization must not be judged solely by the work it produces, for it will be continually hampered by the constant change of new recruits. It should be judged by the men it turns out, just as to-day the *raison d'être* of the teaching hospitals is not so much the quantity of medicine that is practised within their walls as the quality of the doctors they send throughout the land.—I am, etc.,

London, W.1, Nov. 6.

J. B. HARMAN.

Congenital Deformities of Hands and Feet

SIR.—I have recently seen a girl aged 9 years suffering from a condition similar to that described by Mr. Henry Poston in the *Journal* of November 12 (p. 991). The radiographs of her hands are almost identical with those illustrating his case, and her mother's hands show a similar lesion, evidently healed and resulting in marked deformity of the fingers. Dr. Norah Walker drew my attention to the following references which deal with the condition: *Year Book of Radiology*, 1935, p. 60; and 1937, p. 56. Apparently the disease is fairly common in certain parts of East Russia (Transbaikalia), where it is called Urov, or Kashin-Bekov, or Kaschin-Beck disease. Its causation is unknown, but injury is unlikely to be responsible because the bone changes are usually widespread. This is well illustrated in the original paper by W. Graziansky (abstracted in the first of the references quoted above).

Through the kindness of Mr. C. Thurstan Holland and Dr. J. H. Mather I have seen radiographs of two other cases, both living in the Liverpool district.—I am, etc.,

NORMAN B. CAPON, M.D., F.R.C.P.

Liverpool, Nov. 14.

SIR.—In the *Journal* of November 12 (p. 991) Mr. Henry Poston publishes an interesting example of epiphyseal deformity. This deformity usually involves the middle phalanx and leads to stunted development of the affected phalanges. It has been recorded in the middle phalanges of the second, third, and fourth fingers, and a few months ago Dr. Levi submitted radiographs to me of the same condition, with, in addition, changes at both extremities of the diaphysis of the first metacarpal.

It appears to be a congenital familial defect, for it has been noted in a father, three brothers, a sister, and in former paternal generations. All the cases recorded show the condition to be bilateral. It has been found in boys and girls ranging in age from 7½ to 19½ years. The lesion has been described in a number of journals by Thiemann, Esau, Ryffel, Boldero, Shore, and Weil.

The congenital deformities of the hands and feet observed by Mr. E. N. Callum are identical with the condition described by K. Pearson under the title "split foot or lobster claw" (descendants of "Cleppie Bells"). Lewis and Embleton considered 180 cases of "split foot," and point out that the hands, which have never been recorded as affected in the absence of a foot lesion, show one or two main types of deformity. Either it is analogous to the foot lesion, the defect falling mainly upon the centre of the hand, or it affects the pre-axial border of the hand. As a rule the phalanges of at least two or three digits are absent. In the presence of foot malformation one or both hands may escape entirely. The deformity of the hands described by Mr. Callum may occur without the split foot; I published an example of such a deformity in the *British Journal of Radiology* of April, 1936 (p. 265).—I am, etc.,

Birmingham, Nov. 14.

JAMES F. BRAILSFORD.

Control of Small-pox in India: A Suggestion

SIR.—No one familiar with the small-pox mortality figures for British India will dispute that the measures hitherto taken to control small-pox in that country have signally failed. Year after year the ravages of the disease continue to be appalling. During 1936 the deaths from small-pox in Bengal numbered no fewer than 46,267, and in Calcutta alone there were 4,382 deaths. The amount

of sickness and suffering, not to mention the economic loss, which these figures represent is incalculable but can be imagined.

For many years the authorities have pushed vaccination as far as ever it was practicable to do so. I have seen it suggested (and I think it was in an official report) that vaccination would seem to be less effective in protecting the individual in a hot country like India than in temperate climes. However that may be, the effect of vaccination in protecting the community in India has obviously been a lamentable failure.

What a contrast with the state of affairs in our own country! Here the mortality from small-pox has been reduced practically to *nil* since the variety of small-pox known as variola minor came to this country and "took the place" of variola major. In the memorandum on small-pox recently issued by the Ministry of Health (Memo. 215, Med.) it is stated: "The years 1920-1 mark the virtual end of the incidence of variola major as a serious administrative problem, and the beginning of the rise of the minor variety to epidemic proportions."

Now my suggestion is this: that the authorities in India should deliberately introduce and encourage the spread of variola minor in India. This could be done by substituting inoculation with the virus of variola minor for vaccination with calf vaccine. There should be no insuperable practical difficulty. Special legislation might be necessary, and it would probably be wiser to call for volunteers rather than resort to compulsion. Each case inoculated would probably give rise to several other cases, and these in turn would "hand on the torch" to others. There would be no real risk attaching to the experiment, for clinically variola minor is little, if at all, more serious than vaccination. The protection conferred by variola minor against variola major is probably as great as, if not greater than, that conferred by vaccination. The great difference is that the one is infectious while the other is not, and herein would lie the great advantage of variola minor over vaccination in a country like India. Provided the disease could be persuaded to establish itself there is good reason to think that it might oust variola major. If the experiment failed no harm would have been done, while if it succeeded it might be the means of saving countless lives and untold suffering.—I am, etc.,

Leicester, Nov. 11.

C. KILLICK MILLARD.

Decline of Breast-feeding

SIR,—When Dr. Ronald Carter (*Journal*, November 12, p. 1013) states that breast-feeding is the best possible method of infant feeding, his opinion would be accepted in respect of a large number of cases. But the doctor in general practice knows that this does not apply to a considerable proportion of the patients whom he has to deal with. There are patients who, in spite of every encouragement, supplementary feeding, and all the other usually employed devices, prove themselves beyond any doubt incapable of supplying in the natural way any useful contribution to the baby's daily needs. One may speculate on why this should be so. Modern conditions, unsuitable environment, or lack of vitamins in the mother's diet may all have something to do with it. With regard to the last-mentioned possible cause, Dr. Carter says that "there is no shred of evidence to support this hypothesis," but in the leading article on food and nutrition in the *Journal* of October 29 (p. 895) it is pointed out in regard to the

working classes that "practically all its members fall very considerably short in their intake of . . . vitamins."

If the infant normally obtains its supply of vitamins, pre-natally and post-natally, from its mother, and if it be agreed that a serious diminution of vitamins may account for a lessened vitality of the infant, is it unreasonable to suggest this as a cause for the failure of many infants to thrive under modern conditions? So long as routine advice to continue breast-feeding is given to every mother, so long will there be delay in many cases before those responsible bow to the inevitable and permit the long-suffering infant to receive adequate nourishment from another source.—I am, etc.,

HORACE A. NATHAN,
Honorary Secretary.

Kensington Division, British Medical
Association, Nov. 12.

SIR,—The recent correspondence in the *Journal* has proved of great interest to me, but I have refrained from contributing to it in the hope that some expert in milk production would give the benefit of his experience.

Some years ago I was greatly concerned with the difficulties which many women appear to have in feeding their infants in the way that Nature intended they should be fed. I read most of the medical authorities on the subject, but my results continued to be bad, though I carefully carried out their instructions. Thoroughly discouraged as I was, I felt inclined to subscribe to the belief that civilization and the mental make-up of the "modern mother" were inimical to breast-milk production, but I then consulted the real experts on milk production—the dairy farmers—whose living depends upon the mammary output of their cows. Practical knowledge of milk production is possessed by thousands of dairy farmers, and we ought not to allow prejudice or pride prevent us from going to them for information and instruction. The farmer knows well that the cow requires a daily ration of food adequate to maintain health and working capacity. This is known as the maintenance ration; but he gives in addition a milk-producing ration calculated at so many pounds of food per day per gallon of milk yield. This addition to the maintenance ration has a high protein content, for protein is one of the keys to milk production.

A pint of human milk contains about 12 grammes of protein, and this protein can only be obtained from one source—namely, the protein in the mother's diet. The human body is not a perfect biochemical factory and requires approximately 24 grammes of protein intake for an output of 12 grammes of milk protein. Much of the 24 grammes should consist of protein of high biological value. The study of family budgets of unemployed and lowly paid families makes it abundantly clear that many women are unable to purchase even a minimum adequate protein maintenance ration. Is there any wonder, therefore, that they are unable to spare sufficient protein for milk production?

Realization of the basal fact that the woman's diet must contain adequate quantities of protein and the other materials (calcium, etc.) necessary for the manufacture of milk solved the problem of breast-feeding. Very few women on an adequate milk-producing ration fail to feed their infants at the breast, and the disinclination and aversion to doing so change rapidly, when the diet is properly adjusted, to a contented pleasure in the performance of a natural duty towards their offspring.—I am, etc.,

Stockton-on-Tees, Nov. 14. G. C. M. M'GONIGLE, M.D.

Prevention of Breast Infection

SIR.—I have read with great interest Mr. Charles Donald's article on acute infections of the breast (*Journal*, November 5, p. 954). In it he states that the nipple should be washed with warm boric solution immediately before the child is put to the breast. I would suggest that it would be advisable to wash the nipple free from boric solution, with sterile water, before feeding the baby.—I am, etc.,

Dublin, Nov. 9.

ROBERT M. CORBET.

Prognosis of Anxiety States

SIR.—Dr. Frederick Dillon (*Journal*, November 12, p. 1014) is no doubt very adept at reading the unconscious mind, but I feel that he should refrain from attributing to me opinions concerning the value of treatment in anxiety states which I have never expressed and do not hold. It appears to me that the treatment given is only one of the factors of prognostic significance in anxiety states, and not necessarily the most important—a very different thing from saying that it is of no importance whatever. Dr. Dillon's argument seems to be that one is not in a position to draw conclusions about any of these factors unless one can estimate them all—a view that would invalidate practically every prognostic criterion in medicine and surgery. For example, if one were studying the effect of age on the mortality of pneumonia, one's findings would be of no value unless one also obtained details of the types of pneumococci, methods of treatment including nursing, race and physique of the patients, state of nutrition, and so on *ad infinitum*. If one could assess every factor in a case accurately one could be certain of one's prognosis, but it is a commonplace that this ideal state of affairs is rarely attained. Nevertheless, we venture an opinion in most cases.

In my paper I tried only to express views which were supported by facts ascertained by the inquiry, and will repeat that no reliable conclusions concerning the value of treatment could be deduced from the data at my disposal. All the patients received some psychotherapy, even if only the reassurance accompanying the history-taking at the preliminary interview, but prolonged analysis was only given in three cases.—I am, etc.,

London, W.1, Nov. 12.

ARTHUR HARRIS.

Sulphonamide Chemotherapy in Surgical Infections

SIR.—In his articles on sulphonamide chemotherapy in surgical infections (*Journal*, October 22, p. 845; October 29, p. 901) Mr. A. J. Cokkinis emphasizes the need for waiting for "immunity" to develop before therapy is begun in gonococcal infections, does not advocate such a delay in streptococcal infections of the hand, and ignores the fact in other infections. It would appear necessary to know the time taken for "immunity" to develop in certain cases, and it would be interesting to learn how this is estimated. I have used the sulphonamide group of drugs extensively, but unfortunately without elaborate laboratory control. Therapy was started immediately upon admission or as soon as indicated. In approximately 200 cases of diagnosed gonorrhoea in the female various preparations and dosages were employed. In nearly 90 per cent. of the cases the discharge either ceased or was apparently free from the gonococcus in three weeks. Proseptasine was eventually standardized with the following dosage:

Four tablets four-hourly for four days (32 grammes); then three tablets three times a day for three days (13.5 grammes); then one tablet three times a day for eight days (12 grammes). This gives a total dosage of 57.5 grammes.

Practically every case, whatever the preparation or dosage, developed some toxic manifestations, however slight, such as nausea, vertigo, headache, epistaxis, ulnar paraesthesiae, and in one or two cases a heliotrope coloration. One pregnant woman inadvertently received a full dose of magnesium sulphate and developed a deep heliotrope coloration within twenty-four hours. This persisted without any other sign or symptom for some days until her uneventful delivery. It is impossible to categorize relapses, as most of them were probably re-infections. Two cases of gonococcal vaginitis in children aged 9 and 11 did not respond. Cases of streptococcal tonsillitis received one tablet of proseptasine to suck four-hourly upon admission, and recovered rapidly. No response was noted in a number of cases of infective polyarthritis or after the external application of powder or solution to cases of impetiginous infections.—I am, etc.,

Albrighton, Nov. 7.

FRANK R. NEUBERT.

The Occipito-posterior Case

SIR.—When teaching students concerning the use and abuse of obstetric forceps one has usually stressed certain provisos—among others that the occiput must be in an anterior position, the os fully dilated, and the uterus contracting. Dr. David Price (*Journal*, September 17, p. 638), using his reversible pelvic curve forceps, seems to be a law unto himself in this matter. He is apparently quite happy to apply forceps to a head in any position, with os incompletely dilated and in the absence of "pains." When gently rebuked by Dr. B. E. Meek (October 29, p. 919) he shows no sign of penitence, but even appears to revel in his sins (November 5, p. 968). He even goes so far as to state his belief that application of forceps without full dilatation will be a cardinal procedure to the obstetrician of the future.

Why interfere at all? Why not give Nature a chance? She will often succeed where man has failed—and did so in fifty-eight out of 314 cases of "failed forceps" sent into St. Mary's Hospitals, Manchester, during the last ten years. I suggest that the next time Dr. Price is tempted to interfere he should give the patient $\frac{1}{4}$ grain of morphine instead. The result might surprise him.

I have a second bone to pick with Dr. Price. I received the other day from a firm of instrument makers a leaflet advertising a "reversible pelvic curve forceps with jointed pelvic blades designed by Dr. David Price." The forceps is described in some detail and instructions are given as regards application. The last paragraph reads as follows:

"When a large caput succedaneum has formed in a delayed second stage of labour the position of the occiput is not easily ascertained. If application of the forceps, followed by traction, produces no perceptible advance, press upwards and try rotation in the easiest direction. Rotation accomplished, if the occiput is now anterior, it will be found that advance is at once possible and, with the handles well carried forward, a rapid extraction can be made.

"If rotation is not easily accomplished or if, when rotation is accomplished, no advance still occurs, the position of the occiput must be diagnosed by insertion of the whole hand." [The italics are mine.]

Really, Dr. Price, this is going a little too far. In the first place, in my humble opinion, an instrument maker's advertisement is a most unsuitable medium for the

expression of one's views on obstetrics, particularly views so unorthodox as these. Secondly, it is surely a basic principle that diagnosis should precede treatment, and not vice versa.—I am, etc.,

Manchester, Nov. 8. E. A. GERRARD, M.D., M.C.O.G.

Air Raid Precautions

SIR,—I read with interest your leading article in the *Journal* of October 8 (p. 749) and the ensuing correspondence. Emptying hospitals, under instructions from the Ministry of Health, was surely right during the recent crisis, but the idea of treating casualties in vulnerable buildings showed extreme folly and complete ignorance of the effect of modern aerial warfare on present-day masonry. A study of the fighting in Spain and China goes to prove that the effects of incendiary or gas bombs are insignificant when compared with those of the heavy high-explosive variety.

Dr. Clement Francis (October 22, p. 862) undoubtedly, in my opinion, strikes the nail on the head. He says "it is useless to provide the most efficient medical service conceivable if the number of casualties is going to be tens of thousands, all occurring in the space of a few minutes." The chief aim should be to limit in every way the number of casualties. This can only be done by the provision, so far as possible and as soon as possible, of bomb-proof shelters for our civil population. Until some new method of dealing with bombing planes is found which will be so efficient as practically to preclude the risk of aerial bombardment entirely, provision of these shelters must be of paramount importance. Passive resistance to aerial warfare must, in a protracted struggle, be of almost as great importance as the possession of great powers of aerial offence. The fighting forces depend on adequate civil backing. Unless the civilian is trained to resist passively by safeguarding himself or herself, the fighting forces will suffer in efficiency and offensive power. All must serve in a time of national emergency, so the safety and efficiency of the individual is of prime import.

I agree with Dr. W. G. Booth (October 22, p. 862) that control of emergencies should be local, and think that it should be vested in the air raid wardens. Wardens should have prearranged parties ready to deal with gas, fire, or casualties caused by high explosives. While the medical profession must co-operate in all these services, it is mainly with casualties of the latter variety that we are concerned. Doctors and first-aid squads will, of course, be very necessary, but much more than that will be required. Many injured will be buried under fallen masonry, beams, joists, and even steel girders. Skilled artisans must be available who have technical knowledge of building construction—for example, masons, bricklayers, carpenters, and oxy-acetylene cutters—complete with tools, saws, pickaxes, crowbars, levers, ladders, etc., to release casualties buried in the debris of buildings. There must be rapid means of transport: for artisans and tools, lorries; for first-aid squads, motor ambulances. Casualties should be dealt with swiftly and temporarily and conveyed immediately to properly prepared hospitals.

Such hospitals should be bomb-proof even to direct hits. The present hospitals might easily be completely wrecked, with further suffering to the already wounded and the loss of important surgeons, doctors, and nursing staff. The medical services will be invaluable to the State in the event of war, and to do their best work they should be able to operate free from anxiety. These hospitals would be entirely of a surgical nature, and should be looked on as casualty clearing stations. Casualties must not remain

in them for any length of time. As soon as possible they should be evacuated by motor convoy to large decentralized hospitals in wide rural areas where the risk of bombing would be slight compared with that in built-up places. Country mansions with a system of sandbagged hutments spread round would be excellent, as would shooting-lodges in Scotland.—I am, etc.,

Grantown-on-Spey, Oct. 24.

D. M. MARR, M.D.

SIR.—It seems certain that unless an alternative scheme is put forward by an authoritative body wholesale billeting will be the method selected for evacuation of the civilian population in time of war. Although the nation is prepared to accept necessary evils, the people are entitled to ask whether a better alternative cannot be found, even if only for a proportion of the population. To be satisfactory—that is, efficient and economical—an evacuation scheme should: (1) make use of such collective grouping of the population as normally exists; (2) utilize existing buildings and other facilities; and (3) not require constant revision. Taking these points in order, it is obvious that the children attending national schools form groups which it would be desirable to maintain as units under the control of their own teachers. If they are distributed in twos and threes among the inhabitants of country districts supervision and general care must be haphazard, apart from the serious difficulties caused to the households receiving them. Refugee camps have been suggested, but in winter, at any rate, life under canvas, with its problems of water supply and sanitation, presents serious problems.

In many country districts there are large national school buildings which could be adapted as hostels. This would interfere with local education; but in many cases there are church halls which could be utilized as classrooms, failing which it would be easier to erect temporary wooden buildings for this purpose than for living accommodation, owing to the greater requirements of the latter in regard to sanitation and water supply. Billeting arrangements as at present suggested would need constant revision, as households vary from time to time in the number of inmates, and therefore in their billeting capacity, whereas the capacity of the national school buildings remains constant.

The scheme advocated would require a central district committee to select those schools most suitable as hostels, bearing in mind the need of facilities for an augmented food supply. Schools having been inspected and dormitory accommodation determined, the city school personnel (teachers and children) could be allocated according to numbers, dividing the sexes when the numbers are too large to be accommodated as one unit. Subcommittees would be required to deal with problems of equipment, provisioning, and transport; local committees should be formed to co-operate with these subcommittees. Additional staff would be needed, part of which could be recruited locally—for instance, cooks and cleaners. If the national school children were dealt with in this way children attending other day schools might be accommodated in those country houses which have been empty for years, and are likely to remain so, chiefly on account of their size. Youth hostels might house some of the older boys. The schools vacated in the cities would make admirable first-aid posts and clearing hospitals (apart from vulnerability), and could quickly be adapted for this purpose at short notice if each had been individually inspected and if plans had been drawn up for decontamination rooms, etc., and all materials assembled for gas-proofing.—I am, etc.,

Edinburgh, Nov. 8.

ESMÉ HILL.

SIR.—I entirely agree with Mr. A. G. Dickens's letter in the *Journal* of November 5 (p. 965). I have advocated bomb-proof shelters from the first as the only basis for A.R.P., and I would like to urge the leaders of our profession to bring pressure on the Government to put through a scheme without delay and regardless of legitimate expense in London and other big towns. Medical men cannot possibly give adequate attention to casualties unless really safe bomb-proof shelters are provided for them and their patients. If sufficient accommodation is forthcoming for all those who are not likely to be evacuated the majority of casualties will be prevented and the threat of bombing will lose much of its terrors. Mr. Dickens has asked those who are interested to write to him at Keble College, Oxford, and I hope there will be a big response.—I am, etc.,

London, W.14, Nov. 7.

C. WATNEY ROE.

Universities and Colleges

UNIVERSITY OF OXFORD

On November 7 Jean Orr-Ewing, B.M., was elected to an official Fellowship at Lady Margaret Hall.

UNIVERSITY OF CAMBRIDGE

On the nomination of the Faculty Board of Medicine Dr. A. N. Drury, F.R.S., Huddersfield lecturer in special pathology, has been appointed assessor to the Regius Professor of Physic for the year 1939.

UNIVERSITY OF LONDON

Sir Girdling Ball, F.R.C.S., has been elected Dean of the Faculty of Medicine for the period 1938-40.

Sir Ernest Graham-Little, M.P., has been re-elected for the seventeenth consecutive year chairman of the Council for External Students of the University of London.

UNIVERSITY COLLEGE

A special University Lecture on "Intermolecular Forces and Infra-red Spectroscopy" will be given at University College, Gower Street, W.C., by Dr. Jacques Errera, professor of physical chemistry in the Université Libre de Bruxelles, on Monday, November 28, at 5.30 p.m. The chair will be taken by Sir Robert Robertson, F.R.S. The lecture, which will be delivered in English and illustrated with lantern slides, is addressed to students of the University and to others interested in the subject. Admission is free without ticket.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE BUCKSTON BROWNE DINNER

The eleventh annual Buckston Browne dinner to Fellows and Members of the Royal College of Surgeons was held at the College on November 10, with the President, Mr. Hugh Lett, in the chair. Reviewing the activities of the College during the past year the President said the chief event had been the opening of the Bernhard Baron Research Laboratories. Experimental research had become an increasingly important part of the activities of the College during the last ten years. Six years ago it received a great stimulus by the magnificent gift and endowment by Sir Buckston Browne of the Research Farm at Downe, but the laboratories at the Royal College were unworthy of that great institution. Although the College did not know where the money might come from they hopefully drew up plans and prepared estimates of cost. Their hope was justified, for Sir Alfred Webb-Johnson conjured the splendid gift of £30,000 from the Bernhard Baron Trustees. Building was begun in January, 1937; the fourth and fifth floors were reconstructed, and a sixth floor added, and the new laboratories were opened by the Earl of Athlone last December. The excellence of the work that had been done at the Buckston Browne Farm and during the last eleven months in these laboratories must give much satisfaction to the generous donors. Most of the research had a direct bearing on surgical treatment, diagnosis, or pathology.

The College was grateful, Mr. Lett continued, for grants for its research workers from outside bodies, particularly the Medical Research Council, the Rockefeller Institute, and the British Medical Association. These grants were a source of

much satisfaction, not only as a recognition and appreciation of the quality of the work that had been done and the facilities the College could offer, but as a tribute to the Director of Research and Professor of Experimental Surgery, Dr. John Beattie, who, well known for his original work in the field of physiology, was now recognized for his gifts in initiating and directing research. Good progress had been made in the Museum under the direction of the Pathological Curator, Dr. L. W. Proger, and the Assistant Conservator, Dr. A. J. E. Cave. Many valuable specimens had been added, particularly in the sections of osteology and pathology. The pathological work of the Radium Beam Therapy Research had been entrusted to the College, and the secretariat of the Imperial Cancer Research Fund had been transferred there. Mr. Lett acknowledged the College's gratitude to Mr. Braithwaite for securing the bust of Thomas Wormald, who was President in 1865, and to the Middlesex Hospital Medical School for the gift of a fine bust of John Whitaker Hulke, President from 1893 to 1894. In conclusion he referred to the need for cleaning and restoring the College's pictures. The recent alterations to the building and the increasing cost of the Museum and Research Departments had made it impossible to draw on general funds for the purpose, but Sir Alfred Webb-Johnson had put the College still further in his debt by announcing a gift of five hundred guineas from an anonymous donor.

Sir Buckston Browne, replying to the toast of his health, said that it had been his privilege to live through exactly the last half of the nineteenth century, that wonderful century which had done more for the alleviation of man's physical miseries than all previous centuries put together. With this achievement the names of Jenner, Pasteur, and Lister were immortally associated; they were the emancipators of the human body. But above them all was the great figure of Charles Darwin, the emancipator of the human mind. Darwin taught man where he came from, what he was, and what he might reasonably expect to be if he studied the great truths of Nature and the laws of her operations. The call of Darwinism was to the unity of all mankind in a struggle to conquer the evils which menaced its existence and destroyed its happiness—disease and war. As the dinner was a special occasion, a father-in-law entertained by his son-in-law, Sir Buckston asked each guest to accept a silver snuff box, and assured them that a daily pinch of snuff reduced the risks of a cold in the head and other respiratory troubles to their minimum.

The following Fellows and Members were present:

Council.—Professor G. Grey Turner and Professor R. E. Kelly (vice-presidents), Mr. Ernest W. Hey Groves, Sir Cuthbert Wallace, Mr. W. Sampson Handley, Mr. Wilfred Trotter, Professor A. H. Burgess, Mr. Victor Bonney, Professor Graham Simpson, Sir James Walton, Sir Alfred Webb-Johnson, Mr. G. Gordon-Taylor, Sir Charles Gordon-Watson, Mr. R. C. Elmslie, Mr. L. R. Braithwaite, Mr. H. S. Soutar, Sir Girdling Ball, Mr. Seymour Barling, Mr. C. Max Page, Mr. W. H. Ogilvie, Mr. Cecil P. G. Wakeley, and Mr. L. E. C. Norbury.

Fellows.—Dr. Tom Bates, Mr. Lancelot Bromley, Mr. W. Derrick Coltart, Mr. D. R. Davies, Mr. John Foster, Mr. R. H. Franklin, Sir Francis Fremantle, Mr. R. Affleck Greaves, Mr. H. E. Harris, Mr. Kenneth James, Mr. Geoffrey Jefferson, Mr. R. Scott Mason, Mr. T. W. Mimspriss, Mr. Erichsen S. Page, Professor C. A. Pannett, Mr. Bertram A. Pidcock, Mr. A. McKie Reid, Mr. J. E. H. Roberts, Mr. A. E. Roche, Sir Leonard Rogers, Mr. F. F. Rundle, Mr. A. Simpson-Smith, Mr. A. S. Till, Mr. A. Glandon Williams, and Mr. C. P. Wilson.

Members.—Dr. Heward Bell, Dr. D. E. Bedford, Surgeon Rear-Admiral C. M. Beadnell, Dr. H. E. Blake, Dr. H. E. A. Bolders, Dr. C. P. F. Boulden, Dr. E. L. Blount, Dr. Judson S. Bury, Dr. Frank Clayton, Mr. T. V. L. Crichton, Mr. F. N. Doubleday, Dr. F. R. Eddison, Mr. B. J. Frankenberg, Dr. Beaufort Fraser, Dr. S. E. Furber, Dr. T. H. Gardner, Mr. W. Cliff Hodge, Mr. L. D. A. Hussey, Dr. R. C. Jewsbury, Mr. C. E. M. Jones, Dr. W. E. Joseph, Mr. F. G. Layton, Commander Murray Levick, Mr. Windsor Lewis, Mr. A. F. Morcom, Dr. W. D. Newcombe, Mr. E. E. Pochin, Dr. A. E. Potter, Dr. L. W. Proger, Mr. W. Bentley Purchase, Mr. Walton R. Read, Dr. G. R. Rossdale, Dr. Gordon Simpson, Dr. A. W. Stott, Mr. T. Y. Simpson, Mr. W. J. Susman, Dr. J. W. de Wit, Gray Thornton, Mr. T. H. E. Taylor-Jones, Dr. P. H. Whitaker, Mr. Cecil Wilsoo, Sir Charles Wilson, Mr. H. B. Wilson, Dr. J. A. Young, Dr. A. H. Zair.

Also present were Professor R. J. S. McDowall, Professor John Beattie (Director of Research), Mr. Kennedy Cassels (Secretary), Dr. A. J. E. Cave (Assistant Conservator), and Mr. W. F. Davis (Assistant Secretary).

An ordinary council meeting of the Royal College of Surgeons of England was held on November 10, with the President, Mr. Hugh Lett, in the chair.

The following were appointed assessors for the Primary Fellowship examinations to be held over-seas in 1939: at

Lahore, January 2: *Anatomy*, Lieutenant-Colonel F. J. Anderson, M.C., F.R.C.S., I.M.S., professor of surgery in the University of Calcutta; *Physiology*, Lieutenant-Colonel H. S. Anand, M.B., Ch.B.Ed., D.P.H., I.M.S. At Cairo, January 13: *Anatomy*, Professor D. E. Derry, M.B., Ch.B. *Physiology*, Professor Gleb von Anrep, M.D., D.Sc., F.R.C.S.

Dr. A. J. E. Cave was appointed representative of the College on the British National Human Heredity Council, and Mr. C. Max Page on the Fracture Subcommittee of the Voluntary Hospitals Committee for London.

Miss Collard and Dr. H. N. Goadby were appointed Mackenzie Mackinnon Research workers and Mr. G. M. Hill was reappointed for the third year.

Diplomas

Diplomas of Membership and Diplomas in Public Health were granted to the candidates whose names were published in the report of the meeting of the Royal College of Physicians of London in the *Journal* of November 12 (p. 1023).

The following hospitals were recognized under paragraphs 21 and 23 of the Fellowship regulations:

London Homoeopathic Hospital, house-surgeon.
Cornelia and East Dorset Hospital, Poole, recognition extended to July 31, 1941.

The Services

No. 14 STATIONARY HOSPITAL DINNER

The nineteenth annual dinner of the medical officers of No. 14 Stationary Hospital will be held on Thursday, December 8, at the Trocadero Restaurant, Piccadilly, W., at 7.15 for 7.45 p.m., with Colonel C. R. Evans, D.S.O., in the chair. The price of the dinner is 12s. 6d. exclusive of wines. The honorary secretaries are Major-General H. M. Perry and Dr. H. L. Tidy, 39, Devonshire Place, W.1.

Medical Notes in Parliament

The House of Commons this week completed the debate on the Address in reply to the King's Speech and also discussed motions proposed by private members.

New Bills

The Housing (Financial Provisions) (Scotland) Bill was presented on November 9 by Mr. Colville. The same Minister presented on November 10 the Reorganization of Offices (Scotland) Bill. This latter Bill gives effect to the Report presented in 1937 of the Committee on Scottish Administration. The Bill will vest in the Secretary of State for Scotland the functions of the Department of Health for Scotland. One clause provides for the reorganization of the General Board of Control for Scotland.

The Criminal Justice Bill was introduced by Sir Samuel Hoare on November 10. Two of its objects are "to provide new methods and to reform existing methods of dealing with offenders and persons liable to punishment" and "to amend the law relating to the management of prisons and other institutions."

Private Members' Bills were presented in the House of Commons on November 11 by members successful in the ballot. Dates chosen for second reading, titles of Bills, and members introducing are:

November 18, Workmen's Compensation Bill, Mr. Ridley.

November 25, Public Health (Coal Mine Refuse) Bill, Mr. Lawson.

December 9, Workmen's Compensation Acts (1925 to 1934) Amendment Bill (to amend the Workmen's Compensation Acts with respect to miners' nystagmus; to provide for the establishment of medical tribunals of appeal; to make sundry alterations in medical procedure, etc.), Miss Ward.

December 16, Adoption of Children (Regulation) Bill, Miss Horsbrugh.

December 16, Contraceptives (Regulation) Bill (to regulate the public display of contraceptives, etc.), Mr. Simmonds, sup-

ported by Sir Francis Fremantle, Sir Joseph Leech, Sir Henry Morris-Jones, Major Neven-Spence, and Dr. Salter.

February 3, Charitable Collections (Regulations) Bill, Mr. Craven-Ellis.

February 3, Voluntary Hospitals (Relief from Rating) Bill, Mr. H. G. Williams.

The text of the Workmen's Compensation Bill, introduced by Mr. Ridley, was issued on November 15. It includes a provision to substitute for medical referees under the Workmen's Compensation Act a medical board appointed in accordance with regulations to be made by the Home Secretary.

Debate on the Address

The debate on the Address in the House of Commons was continued on November 14 on a Labour amendment. Moving this, Mr. PETHICK-LAWRENCE said that the Labour Party welcomed the announcement of the new cancer campaign, but thought that a still more urgent need was to take drastic steps to cure the cancer in the body politic of the State itself. There was an artificial shortage, exclusive of supplies from abroad, a limitation of home output, and, in some cases, a deliberate destruction of food. He paid a tribute to the scientific men who had brought the question of malnutrition to the front. They had done valuable service to mankind, and had made a lasting contribution to the progress of the world. Dr. M'GONIGLE, the medical officer of health for Stockton-on-Tees, who had been engaged on a study of the health of children of the better-off classes compared with that of city children, had said that the latter were five times as great sufferers from anaemia as the children of the professional classes. In the case of bronchial troubles, city children were ten times more liable to disease than children of the professional classes. He had been amazed at the statistics of Sir John Orr with regard to stunted growth. He had shown that if one compared the average height of a large sample of boys taken from the public schools with a similar large sample of boys from the elementary schools there was a difference of no less than six inches between the one and the other. Mortality figures for this country, given in a book published by the League of Nations, showed that the prosperous districts had a corrected death rate 30 per cent below the average, whereas the poorer districts showed a figure 40 per cent higher than the average. He did not think that anyone denied that malnutrition was largely responsible for these differences. The Prime Minister, last week, had referred to nutrition, and used words which, if they meant anything, surely meant that one of the main causes of malnutrition was not lack of purchasing power but ignorance and possibly negligence on the part of the mothers in the spending of their money. That was a very comfortable doctrine, but the statements of medical officers did not substantiate it. As he (Mr. Pethick-Lawrence) understood it, the position of the Government in regard to the condition of the people was that it was a question of expenses, and that at the present time when money had to be expended on rearmament there was necessarily a conflict between guns and butter.

THE CANCER CAMPAIGN

Dr. ELLIOT said that the Government proposed shortly to introduce a Bill which would make provision for extended arrangements for the treatment of cancer. They anticipated that modern methods of diagnosis and treatment, either by x rays or by operation, would thus be made available to all who suffered from or—and this was an even larger group—who feared this disease. At present only about one-quarter of the cases which might benefit by treatment were receiving treatment on modern lines. Assurances had been received recently that the great research organizations not only would continue their efforts to acquire as much knowledge as possible as to the cause of the disease but would increase them. How to get the early cases to attend the centres was one of the difficulties those administering the schemes would have to face, but, as public opinion had been altered in its attitude towards tuberculosis by national and local schemes, he hoped that people would be persuaded to take advantage of this new scheme, because an early cure would often lead to a complete cure.

Money would be made available to enable the National Radium Trust to acquire more radium, so that the necessary treatment could be given. He had been able to assure the Chancellor of the Exchequer that the life of radium was 2,500 years, making it a fit subject for a small loan. He was at present closely engaged in discussing details of the proposed measure with the various organizations concerned, and he hoped to be able to place the Bill before the House before the Christmas recess.

Referring to nutrition, Dr. Elliot said the number of free solid meals provided by the local education authorities had been more than doubled in the last ten years. The milk-in-schools scheme had proved a success. During last year 200,000 more children had been drinking milk under the scheme, of whom 50,000 or more had been getting it free of charge. There was also the question of the wise choice of food. The injudicious choice of food had done great damage to many sections of the community, and not to the poorer sections alone. A knowledge of the right kind of food, how to choose food, and how to cook food was a very important factor.

Turning to physical education, Dr. Elliot said that new schools and playgrounds were growing up all over the country. The National Fitness Council had now allotted grants amounting to nearly £750,000 to schemes for youth movements, for developing leadership, and for doing by voluntary means what other nations were doing by compulsory means.

With regard to maternal mortality, he had followed with interest the spectacular results that had been obtained by new methods of treatment, but he realized the number and complexity of the problems still calling for investigation. As a result of the Act which the House passed in 1937, nearly 7,500 whole-time midwives were now employed by local authorities in England and Wales, and it had been possible to make orders against any persons who were not certified midwives or registered nurses in forty-four out of 188 areas. In 1937 the maternal mortality rate went down to 3.13, which was a low record.

Mr. COVE said that, reading the reports on nutrition made by the medical officers of health, he got the impression that a large number gave no evidence that they knew the real condition of the nutrition of the children. He might be unfair and unjust, but he got the impression that in some cases at least the reports were written to please the authorities.

Medical News

Air Vice-Marshal Sir David Munro, K.C.B., F.R.C.S.Ed., was elected Rector of St. Andrews University on November 12 with a majority of 118 votes. The other candidate was Admiral of the Fleet Sir Roger Keyes.

The Council of the Royal Society has recommended the following for election as officers at the anniversary meeting on November 30: President, Sir William Bragg; Treasurer, Sir Henry Lyons; Secretaries, Professor A. V. Hill and Professor A. C. G. Egerton; Foreign Secretary, Sir Albert Seward. The following members of the medical profession are among those recommended for election to the Council of the Society: Professor Major Greenwood, Professor John Mellanby, and Professor W. W. C. Topley.

The next course of lectures on tropical hygiene for men and women outside the medical profession proceeding to the Tropics will be given by Mr. H. H. Clay, Professor R. T. Leiper, F.R.S., and Sir Malcolm Watson at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., from Monday, November 28, to Friday, December 9 (Saturday and Sunday excepted), from 4 to 5 p.m. Applications for admission to the course, the fee for which is £1 1s., should be made to the secretary of the London School of Hygiene and Tropical Medicine.

The British Postgraduate Medical School announces that Professor W. W. C. Topley, F.R.S., will deliver the Kettle Memorial Lecture on "The Place of Pathology among the

Medical Sciences" at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Thursday, November 24, at 5 p.m.

The next quarterly meeting of the Royal Medico-Psychological Association will be held at 11, Chandos Street, Cavendish Square, W., on Thursday, November 24, at 2.30 p.m. At 3 p.m. the nineteenth Maudsley Lecture on "A Revaluation of Psychiatry" will be delivered by Professor D. K. Henderson at 26, Portland Place, W.

The annual clinical "At Home" of the Royal Dental Hospital of London will be held on Saturday, November 26, at 3 p.m., and the dinner of the past and present students of the hospital will be held at the Trocadero at 7.30 p.m.

The first winter meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., on Friday, November 25, at 8.30 p.m., when Colonel L. W. Harrison and Dr. Margaret Rorke will speak on "Venereal Disease Control in Scandinavian Countries."

The annual meeting of the British Health Resorts Association will be held at 28, Portland Place, W., to-day (Friday, November 18), at 4 p.m., with the president, Lord Meston, in the chair.

A joint meeting of the Medico-Legal Society and the Section of Psychiatry of the Royal Society of Medicine will be held at 26, Portland Place, W., on Thursday, November 24, at 8.30 p.m., when a discussion on "The Place of the Psychiatrist in Relation to the Administration of the Criminal Law" will be opened by Dr. R. D. Gillespie and Dr. Denis Carroll (for the Royal Society of Medicine) and Mr. Roland Burrows, K.C., Recorder of Cambridge, and Dr. Letitia Fairfield (for the Medico-Legal Society).

In view of recent developments in methods of treatment of respiratory paralysis the London County Council has decided to hold a demonstration of various types of cabinet and other respirators in the conference hall, County Hall, Westminster Bridge, S.E., on Wednesday, November 23. Any members of the medical profession will be welcome to attend the demonstration between the hours of 10 a.m. and 1 p.m. and 2 p.m. and 4 p.m.

The following medical men were elected mayors on November 9: Dr. H. C. Barraclough (Lowestoft); Mr. S. A. Boyd (Hampstead); Dr. W. E. Moore Ede (Worcester); Alderman I. Flaek (Radcliffe); Dr. B. L. Hodge (Malmesbury); Alderman C. L. Katal (Finsbury); and Dr. R. W. Pearson, M.C. (Arundel). Dr. Moore Ede was re-elected.

The King has approved recommendations by the Council of the Royal Society for the award of the two Royal Medals for the current year to Dr. Francis William Aston, in recognition of his discovery of the isotopes of non-radioactive elements, and to Professor Ronald Aylmer Fisher, in recognition of his important contributions to the theory and practice of statistical methods.

EPIDEMIOLOGICAL NOTES*

Acute Poliomyelitis

The fall in the incidence of poliomyelitis in England and Wales recorded last week has been maintained but not increased, the number notified remaining at 70. In London notifications rose from 4 to 11, and in Scotland from 3 to 5. The counties chiefly affected were London 11 (Battersea, Lewisham, Westminster, and Woolwich 2 each; Chelsea, Kensington, and Wandsworth 1 each); Lancaster 6 (Liverpool 2, Eccles, Lancaster, Manchester, and Urmston 1 each); Essex 5 (Harwich 2, Wanstead, Tendring, Braintree rural 1 each); Glamorgan 5 (Cardiff 2, Penarth 2, Cowbridge rural 1); Lincoln 5 (Gainsborough, Gainsborough rural, South Kesteven, Scunthorpe, Spilsby 1 each); Oxford 4 (Oxford 2, Bullington and Witney 1 each); Southampton 4 (Portsmouth 1, Winchester 2, Ringwood and Fordingbridge 1). The 5 cases in Scotland occurred in Lanark County 2, Edinburgh 2, and Dumbarton 1.

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

In the accompanying graph are given the numbers notified each week in England and Wales, London, and Scotland respectively from July 3 to November 5. The average number notified weekly in the immediately preceding four-week period was England and Wales 3, London 1, and Scotland between 1 and 2. The rapid rise in incidence in England and Wales suggested an outbreak of greater magnitude than is usual in this country, but by the middle of August it had reached its peak. Contrary to expectation there was a recrudescence of the disease in the early weeks of October, culminating in a second peak in the third week equal in height to the August

Weekly notifications of acute poliomyelitis from July 3 to November 5, 1938.

peak. The occurrence of two periods of maximal incidence of acute poliomyelitis in England and Wales is unusual and may conceivably be related to the abnormal spell of hot dry weather experienced in October. The distribution of the disease at that time was fairly widespread: while Essex remained the chief endemic focus, fresh outbreaks were being reported in Glamorgan, Yorkshire, and Sussex.

In London the same explosive character was not encountered, although there were two periods of maximal prevalence, the first showing a lag period of fourteen days after that of England and Wales and the second coinciding with it. (The height of the second peak for the whole country was largely due to the increase in London.) The incidence curve for Scotland conforms more or less to the London curve, except that there was no recurrence in October save for a trifling rise in the week under review, while its rather flattened peak coincided with that for the whole country, not with that for London.

In Holland the number of cases in the week ended October 29 fell from 33 to 19: of those 11 were in the Province of South Holland (4 in the district of Rotterdam). In France 164 cases were recorded in September, compared with 81 in August and with 105 in September, 1937. In the first fortnight of October 110 cases were reported in Finland as against 92 in the preceding two-week period.

Enteric Fever

In England and Wales notifications of enteric fever rose from 19 to 21 and in London from 1 to 4 (Chelsea 2, Hackney 1, Lewisham 1). While no fresh outbreaks have to be recorded the sporadic cases have occurred over a wide area. Only in three towns—London 4, Liverpool 2, Boston 2—have more than one case been notified during the week. There was one death in the 126 Great Towns (at Croydon). The two cases recorded in Scotland were in Dunfermline and Lanark county and there was one death in Glasgow.

Primary and Influenzal Pneumonia

A slight increase was recorded for England and Wales, 583 as against 578; and for London, 75 as against 65. The main counties affected were: Lancaster 84 (Manchester 31, Liverpool 10); Yorks (West Riding) 51 (Sheffield 19, Leeds 7); London 75 (Poplar 9, Islington 8, Bermondsey 6, St. Pancras and Woolwich 5 each); Warwick 37 (26 in Birmingham); Durham 34 (12 in Sunderland); Stafford 30 (Walsall 5, Wolverhampton 6). Of deaths from influenza in the Great Towns 7 were in London, 3 in Rochdale, and 2 each in Oldham and Walthamstow; of the 272 cases of primary pneumonia in Scotland 183 were in Glasgow. The single death from influenza occurred in Glasgow. Of the 33 inmates of a nursery at Hexham (Northumberland) 6 died from bronchopneumonia and the remainder have been isolated at the Walkergate Isolation Hospital in Newcastle whilst the nursery is being disinfected in readiness for reopening. It has not yet been disclosed what the causative organism was or why the infection was so lethal.

Diphtheria and Scarlet Fever

A small increase in notifications of diphtheria was reported for England and Wales, and a small decrease for London. In Scotland notifications decreased from 274 to 253. Towns chiefly affected were: London 145 (Poplar 16 (13), Islington 19 (9), Southwark 10 (4)), Liverpool 48 (59), Bristol 33 (23), Leeds 31 (19), South Shields 25 (21), Sheffield 26 (37), Birmingham 24 (38), Leicester 22 (15), Manchester 20 (28). Of the 19 deaths in the Great Towns 2 each were in London, Plymouth, and Stoke-on-Trent, and 1 each in Croydon, Bolton, Bournemouth, Bootle, Cheltenham, Leeds, Liverpool, Leicester, Great Yarmouth, Merthyr Tydfil, Sheffield, Smethwick, and West Ham. Of the 4 deaths in Scotland 3 were in Glasgow and 1 in Edinburgh. At the time of going to press reports indicate a continued increase of diphtheria of a virulent type in Glasgow and Bristol. Of the 25 cases notified in South Shields 9 were carriers: there were no deaths during the week (2 in the previous week). To date this year there have been 476 cases of diphtheria with 58 deaths recorded in South Shields.

Notifications of scarlet fever rose from 2,000 to 2,040 in England and Wales, but fell from 192 to 168 in London. In Scotland notifications fell from 411 to 403. The principal towns affected were: Liverpool 62 (50), Manchester 28 (56), Birmingham 38 (29), Bristol 33 (44), Newcastle 29 (14), Leeds 28 (35), Sheffield 25 (37), Nottingham 25 (19), West Ham 22 (18), York 20 (11). Of the 168 cases in London 13 (10) were in Islington, 13 (3) in Stepney, 13 (26) in Wandsworth, 16 (9) in Poplar, and 12 (11) in Battersea. In the Great Towns of both countries there was 1 death (in Edinburgh).

Measles and Whooping-cough

Of the 22 cases of measles notified in London there were 4 each in Stepney and Lambeth and 2 each in Fulham, Westminster, Islington, Shoreditch, and Southwark. The single death recorded occurred at Wolverhampton. Of the 14 cases of measles reported in Scotland 3 were in Orkney. There were no deaths. In London 141 (146) cases of measles were notified, chiefly in Battersea 18, Kensington 11, Southwark 11, Finsbury, Islington, and Hackney 10 each. There were 4 deaths (1 each in London, Heston and Isleworth, Reading, and Leicester). In Scotland notifications rose from 178 to 203, of which 158 (134) were in Glasgow, 15 (12) in Lanark county, 11 (4) in Edinburgh, and 11 (6) in Paisley. There was one death in Glasgow.

Cholera and Plague

During the week under review there were 418 (568) cases of cholera and 229 (282) deaths in the Central Provinces of India, 324 (270) cases and 136 (128) deaths in Bombay Presidency, and 104 (218) cases and 51 (97) deaths in the United Provinces.

In India during the same week there were 155 (43) cases of plague and 13 (6) deaths in the Central Provinces, 30 (47) cases with 15 (23) deaths in Bombay Presidency, 17 (11) cases and 17 (8) deaths in Madras Presidency, and in Burma 43 (67) cases with 31 (65) deaths.

INFECTIOUS DISEASES AND VITAL STATISTICS

No. 44

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 5, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash—denotes no cases; a blank space denotes disease not notifiable or no return available.

Letters, Notes, and Answers

LETTERS, NOTES, ETC.

A Jubilee Volume

We have received from Bayer Products Ltd. a copy of a jubilee volume entitled *Fifty Years (1888-1938) of Bayer Remedies*. The volume is beautifully produced and the illustrations are particularly noteworthy. Much information of general historical medical interest is given regarding the development of the synthetic drugs which to-day are of such dominant importance in therapeutics. The development in this field has been so rapid that everyone has been too busy testing new discoveries to spare time to write the history of their origin. This volume contains many interesting notes regarding the early work of Behring and of Ehrlich, laboratory notes on the discovery of plasmoquine and atabrin, the struggle attending the introduction of local anaesthesia, etc. Phenacetin was the first synthetic preparation introduced into medical science bearing the name of Bayer, and it is an interesting fact that only fifty years separates these early stages of synthetic organic drugs from the recent triumphs of organic chemistry in the synthesis of vitamins and hormones.

Tuberculosis and Post-partum Haemorrhage

Dr. J. M. MACPHAIL (Middlesbrough) writes: I have noted that women who are not themselves tuberculous but who belong to a tuberculous family readily succumb to post-partum haemorrhage, or puerperal septicaemia, a short time after a confinement. To all appearances they may have been in perfect health, and this makes their deaths all the more tragic. I refer here not to the patients with an acute pleurisy which is the beginning of an acute tuberculosis, but to the apparently healthy young women who suddenly and unexpectedly succumb. Those who scoff should remember that irregular menstruation is very common in young tuberculous people.

Diagnosis of Malaria

Dr. J. E. FOLEY (Sandown) writes: We have all our own methods for the diagnosis and treatment of malaria, but I would like to stress the importance of not placing too much faith in a negative blood slide and of remembering that each attack must be followed up with adequate treatment, irrespective of how much annoyance, unpopularity, and criticism one lays oneself open to. In cases in which a blood film is negative quinine is too often withheld or not given in adequate dosage. We have specific remedies for malaria, and it is of the utmost importance that these drugs should be administered as early as possible; malaria is, in fact, our most urgent medical emergency in the East.

Choice of Careers

The Ministry of Labour has published new editions of the pamphlets on Librarianship (No. 11), Nursing (No. 17), and Secretarial Work for Women (No. 19), which are part of the series entitled *Choice of Careers* compiled by arrangement with the Incorporated Association of Headmasters and Headmistresses of Public Secondary Schools. Each of the pamphlets sets out the nature of the work, the qualifications needed, the methods and cost of training, and the prospects in the various branches of the occupation. They may be obtained from H.M. Stationery Office or through any bookseller, price 3d. (Nos. 3, 11, and 19) and 4d. (No. 17).

The Ostermilk Book

The Glaxo Laboratories, Ltd., of Greenford, Middlesex, announce a new and revised edition of *The Ostermilk Book*, the third since its first appearance just over eighteen months ago. It is intended for the guidance of mothers in the care of themselves and their infants. Copies of the book will be sent on request to any medical practitioner.

Corrigendum

Surgeon Lieutenant S. GAY FRENCH, R.N., writes: I much regret that through an error of typing the paper by Surgeon Lieutenant-Commander Horan and myself published in the *Journal* of November 5 (p. 942) was headed "Sulphonamide in the Treatment of Acute Mastoiditis." As the context of the paper shows, the heading should have been "Sulphonamide in the Prevention of Acute Mastoiditis." We know of no treatment of the acute disease, except the usual surgical measures. I apologize to any reader whom this error may have misled.

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology
Westcent, London.

SECRETARY, Medisecra Westcent, London.

The address of the B.M.A. Scottish Office is 7, Drumshough Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúirí na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin.)

QUERIES AND ANSWERS

Case for Diagnosis

Dr. E. S. HAWKES (Budleigh Salterton) writes: I should be grateful for any suggestions as to diagnosis and treatment of the following case. A schoolgirl aged 16½ years has for ten months been running a temperature of 99.2° to 100.2° F. about the middle of the day; the temperature then drops to about normal. There are no other physical signs, except a slight decrease in superficial and deep reflexes. The girl looks ill and has extreme lassitude. I am quite satisfied that there is no question of neurasthenia. A consultant physician and a skilled pathological examination failed to reveal any sign of disease; yet the girl is obviously ill.

Varicose Veins

"M.E.D." writes: A female patient of mine has had large varicose veins in both legs injected on about twelve occasions without any result. The solution used was quinine and urethane. Can anyone suggest the reason for this, and if it would be advisable to try some other solution?

Cattle Ringworm in Man

Dr. E. S. HAWKES (Budleigh Salterton) writes in reply to Dr. Stewart (*Journal*, November 12, p. 1027): Most of these cases can be cleared with ung. cuprosal (Duncan Flockhart and Co.) More severe lesions, with secondary sepsis, should be cleaned with frequent applications of eusol by day, the ointment being used at night. The only case that I have had that failed to respond to this treatment yielded to ultra-violet irradiation in increasingly strong doses.

Protection of Eczematous Face

Dr. R. V. MONAHAN (Navan) writes in reply to Dr. D. Braham (*Journal*, November 12, p. 1027): I would suggest that a close study of these cases will in most instances reveal some evidence of a lack of thyroid secretion—dandruff, dry or falling hair, outer half of eyebrows missing or badly nourished; dry, pale, thick, inelastic skin; slow pulse, etc. These patients will do remarkably well when the deficiency is corrected and they are kept on a maintenance dose of thyroid. I give them a three-weeks course, repeated indefinitely with an interval of one week between each course. The necessary dose of thyroid varies, but the pulse rate should be pushed to the region of 80 a minute and should never be allowed to exceed 90 a minute. A daily dose of 5 to 10 grains of fresh gland extract will usually be sufficient; later, when the symptoms of eczema have disappeared, a smaller dose will suffice to keep the patient at a normal level; possibly 1 or 2 grains a day will be ample.

*Surgical Treatment of Puerperal Infection. P. Ballard.—p. 529.

Surgery of Puerperal Infection.—After a discussion of medical treatment, in which vaccines are not praised but rubiazol is commended, Ballard decides against curettage for metritis and in favour of laparotomy for generalized peritonitis following puerperal infection. The merits of hysterectomy and of the venous ligature operations are examined; the former is thought to have some place in cases of infected myomata, uterine infarction after abortion, or in repeated post-partum haemorrhage.

- *New Method for Measuring Haemo-bactericidal Power; Its Practical Applications. Jeanneney, Castanet, and Cator.—p. 1305.

Haemo-bactericidal Power.—The authors describe in detail their technique, which consists essentially in placing known dilutions of a standard organism in contact with measured quantities of citrated blood on a series of slides and observing the effect on the organisms through the microscope. They claim that this method provides a means for estimating the resistance of the body to infections.

*Observations on Some Grave Cases of "Pulmonary Embolism." J. Fauvet and A. Monsaignon.—p. 1315.

Blue Phlebitis.—Grégoire describes a case of his own and mentions several others. He considers that the gravity of this condition is not usually sufficiently appreciated, for it is essentially a complicated phlebitis, since the arterial system is involved as well as the venous, so that in addition to the ordinary dangers of embolism the possibility of gangrene due to arterial spasm and arrest of the arterial blood flow may arise.

"Pulmonary Embolism."—The authors describe sixteen cases of "pulmonary embolism" so called, or, as they prefer to regard them, sixteen cases of "dramatic and unexpected post-operative accidents" usually attributed to pulmonary embolism. Of these ten died: three immediately—that is, before treatment of any sort could be applied; four in a few minutes; and three after a longer period, during which various forms of treatment (atropine, morphine, adrenaline, ephedrine, injection of stellate ganglion) had been tried without avail. Six cases were cured, five permanently; the sixth died in coma the day after apparent cure, without any further signs in the lungs.

Rickettsioses in South Africa.—This is an important paper dealing mainly with the serological characteristics of the three South African rickettsioses (tick-bite fever, sporadic typhus, and louse typhus). There is evidence that these three diseases form a group by themselves, having closer affinities with one another than with the rickettsioses of other countries.

 Folliculitis Naris Perforans: Case Report. R. B. Palmer.—p. 429.

Pruritus Ani.—E. Hollander reports a new treatment of primary pruritus ani. He states that the idea is based upon the observation that cutaneous syphilis did not involve portions of the skin that had been tattooed red with mercuric sulphide (cinnabar). The technique is fully described. It involves cleansing of the skin with metaphen, anaesthesia with procaine hydrochloride, antiseptic with phenolated petrolatum, and tattooing of cinnabar suspended in water into the skin. Twenty-six cases have benefited, two are well after one year, and the treatment has been used with success in cases of pruritus of vulva and scrotum.

Active Sweat Glands.—The secretion and function of sweat, its association with general bodily manifestations, and methods of investigation are reviewed by H. M. Buley. The difficulty of catheterization of a single sweat gland, and of deducing much from this when successful, is stressed. A small investigation chamber is described, and the results of microscopical observation of sweat production from the pores of the skin of the fingers are discussed. It appears that sweat is discharged on to the skin at irregular intervals, possibly by muscular contractions, and that a drop of a certain size must form before expulsion takes place. Too small an amount of fluid cannot be discharged and is reabsorbed into the glandular ducts by peristaltic movements.

Dermatitis and Stomatitis from Mercury Amalgam.—Traub and Holmes report two patients affected by the mercury of

amalgam fillings and indicate that, unless cheap copper amalgams are used, there is very little risk of such a stomatitis being produced by mercury in the mouth as a result of solution or vaporization from the amalgam. The authors are of the opinion that the condition is a contact dermatitis or stomatitis and is not due to the absorption of mercury. They believe that this contact occurs when the dentist squeezes out any excess of mercury while kneading the material into the cavity, the reaction following after a few hours and being localized at the contact areas. In one case the patient was also sensitive to mercurial ointment applied to the skin. The literature on the subject is reviewed, especially the observations of Fleischmann, who conducted a medical centre in Berlin specially for the study of cases of this kind. The authors are of the opinion that mercury poisoning from amalgam fillings is more likely to be detected by examination of the urine than by examination of the stools, but point out that many apparently normal persons excrete mercury in the urine.

 Congenital Haemolytic Anaemia with Normal Fragility of Red Blood Cells. E. Schiff.—p. 264.
 *Hydatid Cyst of Spinal Canal successfully treated by Operation. J. S. Y. Rogers and G. R. Tudhope.—p. 269.

Ascariasis.—Williams points out that this condition is practically world-wide in distribution and abounds where sanitation is primitive and where there is a low standard of living. Infection may take place at any time after birth. The diagnosis can only be made by finding the worms or their ova in the stools. In a small baby the symptoms are generally those of enteritis, as the alimentary tract is more irritable than is the case in older children, in whom as a rule the symptoms are vague. It would seem that ascariasis may eventually produce an immunity, so that adults may harbour many worms without obvious inconvenience. Oil of chenopodium is the safest and most effective drug for children and is given with a fluid diet and magnesium sulphate.

Hydatid Cyst of Spinal Cord.—This is a description of a child, aged 9, who suffered from constant pains and weakness in the lower limbs. An x-ray examination after the injection of lipiodol into the spinal column showed a block at the level of the first lumbar vertebra. At operation a solitary hydatid cyst was removed and complete recovery followed.

 Mechanical Intestinal Obstruction complicating Pelvic Inflammatory Disease. M. H. Levine and G. Blinick.—p. 498.
 Tuberculosis of Stomach. O. T. Clagett and W. Walters.—p. 505.

Phantom Limb Pain.—This is a description of ten cases in which the painful sensations of severe cold and muscular cramps in the ablated limb had been relieved for varying

periods by the injection of procaine hydrochloride in the region of the stellate and upper thoracic sympathetic ganglia.

Hepatic Function.—The value and limitations of the various tests for hepatic function are discussed. Evidence is advanced of the benefit resulting from dextrose therapy as a pre- and post-operative measure in patients showing impaired hepatic function. The close relationship between hepatic and renal function is emphasized. From their observations the authors conclude that post-operative thyroid crisis is associated with liver failure. The routine post-operative administration of dextrose to replace glycogen depletion, combined with lecithin if repeated sugar estimations show that the dextrose is not being absorbed, reduces the mortality from this cause. Adequate oxygenation, which can be increased by the direct administration of oxygen or by transfusion post-operatively, is also beneficial in relation to liver function.

Intractable Bronchial Asthma.—Improvement has been obtained in eleven cases, which before bilateral resection of the posterior pulmonary plexus had persisted in a condition of status asthmaticus despite thorough medical treatment and were therefore totally incapacitated. Operation is considered justifiable as a means of ameliorating the symptoms of patients in this group, and results in a reduction of the amount of sputum and a decrease in the degree of emphysema, although minor spasmodic attacks—which can be controlled by ephedrine—occur from time to time.

British Journal of Dermatology and Syphilis

London vol. 52 August-September, 1938

- *Recent Advances in Leprosy and Methods Adopted for Dealing with Problems in France. C. Flaudin.—p. 359.
- *Aetiology of Pemphigus Vulgaris and Dermatitis Herpetiformis (Dühring's Disease): Clinical Experimental Study. A. Dostrovsky, I. Gurevitch, and H. Ungar.—p. 412.
- *New Technique for Epilation of Scalp. E. H. Molesworth and H. L. Brose.—p. 435.
- Four-area Method in X-Ray Epilation of Scalp. S. Cochrane Shanks.—p. 440.
- *Match and Match-box Dermatitis. R. Klaber.—p. 451.

Leprosy.—Epidemiology, contagiousness, and early diagnosis by clinical observation and by a chaulmoogra oil intradermal injection test are discussed. The allergic factor in the disease and the importance of finding the true bacillus are stressed, and mention is made of the value of incision of the lobe of the ear in the search for bacilli and of the intravenous injection of methylene-blue as showing other parts of the skin which are heavily infected. The author recommends the intravenous injection of a colloidal suspension of a cholesterol chaulmoogra compound, the administration of which can even be continued during a feverish attack. In conclusion, he appeals for better education of the public and of lepers on leprosy in all its aspects.

Pemphigus Vulgaris and Dermatitis Herpetiformis.—This is a review of the aetiology, incubation period, and period of development in pemphigus and dermatitis herpetiformis. The authors describe their technique for injecting vesicular contents and extracts of vesicular wall into the cisterna, brains, and veins of rabbits. The symptoms of the resulting disease and those of simple brain injury in rabbits are described. The authors emphasize the difference between spontaneous encephalitis in rabbits and the disease affecting the rabbits they injected, the difficulty in correlating different results of animal experiments with apparently similar cases, and the possibility that the filter-passing virus producing the positive results in their cases is present in 43 per cent. of cases of infection.

Epilation of Scalp.—Molesworth and Brose report the results of experiments to measure the accuracy of the Adamson-Kienböck five-point method of x-ray epilation, and show that there is an error of plus or minus 20 per cent. They suggest a method based on the results of experiments with a skull on a rotating plate exposed to x rays; the patient sits on a revolving plate with the head in a rest, so that the occipital

and frontal centres of the old method lie in a horizontal plane and the vertex is the centre of rotation.

Match and Match-box Dermatitis.—The author discusses the chemistry, history, and geographical aspects of match-box dermatitis. He reports the results of patch tests on himself and another distinguished dermatologist, showing that the irritant is phosphorus sesquisulphide (P₄S₃) combined with heat, humidity, and other factors—hypersensitivity, hyperhidrosis, and handling the substance. He indicates that the areas of election are on the thighs near the pockets and on the fingers and thenar eminences, and that there is often a spread to the face and eyelids.

- *Urinary Calculi developing in Recumbent Patients. I. N. Pyrah and F. S. Foxworth.—p. 97.
- *Periodicity in Cancer and Other Neoplastic Diseases (450 Cases). J. H. Douglas-Webster.—p. 113.
- *Anterior Basal Meningioma. W. R. Henderson.—p. 124.
- Case of Oesophageal Polypus accompanied by Tumour of Accessory Thyroid Gland. E. C. Chubb.—p. 193.

Reconstruction of Lower Oesophagus.—A new method of anastomosis is described which avoids suture of the oesophageal wall and minimizes the risk of post-operative leakage. The oesophagus—with a flanged rubber tube inside it—is passed through an opening in the stomach wall, which is then invaginated around the outer surface of the oesophagus above the flange. The tube is brought to the surface through a gastrotomy opening and later removed.

Recurrent Dislocation of the Shoulder.—A description of the pathological basis for the author's operation, and an illustrated description of the operative technique, are given.

Gastroscopic Appearances.—This communication consists almost entirely of a series of useful illustrations of the normal and pathological appearances obtained by gastroscopy.

Infective Osteomyelitis of Spine.—This is an analysis of twelve cases. Attention is drawn to the small amount of sequestration in the type of disease affecting the neural circles and laminae and transverse processes, and the risks of misdiagnosis in this type owing to the negative x-ray appearances in the early stages, the small focus of bone involved, and the absence of new bone formation.

Urinary Calculi in Recumbency.—In aseptic cases these calculi may often be caused to fragment and disappear by the combined use of active movements and hydrotherapy together with an acidogenic diet.

Periodicity in Cancer.—Periodicity in recurrences has been traced in 282 cases of carcinoma and in thirty-four cases of sarcoma. The most usual term is eight months, though many half periods have been seen in sarcoma and Hodgkin's disease. Should a latent period occur, recurrence has followed as if the period had been active. Many patients have died at or close to a periodical maximum. It is suggested that these observations are consistent with the theory that a virus plays the part of a cell stimulant.

Anterior Basal Meningioma.—This is a description of the syndrome due to meningioma arising from the olfactory groove, the tuberculum sellae, and the inner or outer part of

A thorough investigation

(reported in "The Analyst," 1936, Lxi, 310.)

could find no tea on the market which was free from tannin

The following facts about tea and tea tannin have been established by recent clinical and laboratory experiment:—

- [A] Tea as normally drunk is harmless and has no ill effects whatever on the human body. The amount of caffeine and tea tannin in tea is pharmacologically small.
- [B] Tea tannin is a different substance from the tannic acid of the Pharmacopœia, which is a Pyrogallie tannin, and the two should not be confused.
- [C] Clinical experiments have shown that the action of tea tannin is very much milder than that of tannic acid, and the different composition of the two tannins is proved by the fact that the tannic acid of the Pharmacopœia is about 25 times stronger as an acid than tea tannin.
- [D] Many common beverages besides tea contain similar tannins and in comparable amounts.
- [E] If there were any teas completely free from tannin, they would be almost entirely tasteless.

LEMBAR JUSTIFIES THE DOCTOR'S HIGHEST RECOMMENDATION

COMPOSITION

| | % Composition |
|---|---------------|
| Natural Lemon Juice | 35.0 |
| Cane Sugar | 25.0 |
| Glucose (Dextrose) | 4.0 |
| Sol. Extracts Barley (Maltose and Dextrin) | 5.75 |
| Starch | 2.25 |
| Water | 28.0 |

100 gms. provides 154 Calories.

Tested and approved by a leading London Hospital. Prescribe it for any condition in which lemon juice and barley water are allowed.

RAYNER'S

LEMBAR

Made from finest fresh lemons, good Scotch barley and Glucose (with cane sugar). More efficient, better flavour and more economical than ordinary lemon and barley. *A bottle makes a gallon.* It keeps indefinitely.

SAMPLE sent with pleasure, also useful booklet with special diet sheets and sickroom recipes from a London Hospital. Write to Rayner & Co., Ltd., Medical Dept. B, London, N.18.

2/- a bottle at all leading chemists and grocers.

130 Years Consistent recommendation by the medical profession

Robb's Nursery Biscuits provide a high nutrition factor, offering a balanced vitamin A, B, C, D content which ideally suits the special demands of the growing infant from 6 months up to school age. "Robb's" were evolved by Dr. Golding, the founder of Charing Cross Hospital, and are made from ingredients of the highest quality including rich full-cream dairy milk and the finest wheat and malt. A surprising rate of progress in the condition of the infant is invariably observed after "Robb's" have been prescribed.

Clinical samples free on request.

GIVE YOUR PATIENTS Therapeutic Sunlight the Year-round

THERE is no reason, now, why you should be without the benefits which dependable quartz-mercury Ultra-Violet-Light equipment brings to both physician and patient.

Your investment in the entirely new, more efficient, lower-priced Victor Model "F" Lamp would prove profitable both clinically and economically because:

1—There is such a wide variety of conditions in which Ultra-Violet irradiation can be employed as a basic or adjunct therapeutic measure and

2—The simplicity and sturdiness of the Victor Model "F" Lamp bespeak long, trouble-free life with minimum operating expense.

Send for abstracts from recent authoritative literature; read them and, also, an interesting booklet which describes fully this most recent development in the field of Ultra-Violet, the Victor Model "F" Lamp. Learn what a small financial outlay is required to have one of these splendid units installed. Simply write for Pub. AY3—naturally there is no obligation.

De KUYPER'S HOLLANDS

Distilled with the Juniper berry from genuine malt liquor. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from all irritating properties.

It can be described as carminative, anti-spasmodic and a stimulating diuretic, valuable in many conditions and can be safely taken with regularity.

Distilled by the same family for 241 years.

Scientific Construction makes them *highly efficient*

COZY stoves burn open or closed on ordinary kitchen coal, and are guaranteed to burn 12 hours without attention. All doors are made to fit perfectly.

The amount of air required to ensure complete gas combustion depends upon the fuel used. The air regulating device in COZY STOVES, operated by a dial, is most efficient.

Coal not burnt to ashes still gives off heat. By pulling out the ashpan it is easily done. The new patent Boiling Grate in all large size COZY stoves prevents this and very little but the dead ashes fall through.

COZY STOVES are scientifically designed to give maximum heat with minimum fuel consumption during the whole 24 hours. For efficiency, adaptability, and economy, YOUR home needs a COZY. There's a wide range of models available to suit all requirements.

Write to a Catalogue or see them at your local dealers.

COZY STOVES are available on easy terms.

Illustrated Brochure on application to the Medical Superintendent, The Old Manor, Salisbury.

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNENT, M.D., M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm gardens and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent Telephone No. 2356 and 2357 (Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES for NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided.

As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Supt.: P. K. McCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law. Tel.: Dumfries 1119.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — WOODBRIDGE, SUFFOLK

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW.

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the
RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 216 (Toll Call from London).

Proprietors: The Norwood Sanatorium, Limited.

RUTHIN CASTLE, NORTH WALES

A Private Hospital or Clinic for the diagnosis and treatment of Internal Diseases (except Mental or Infectious Diseases). The Clinic is provided with a full staff of doctors, bacteriologists, chemists, radiologists, dietists, nurses, masseurs, and masseuses.

The surroundings are beautiful. The climate is mild. There is central heating throughout. The annual rainfall is 30.5 inches, that is, less than the average for England.

The inclusive weekly fees are from 15 guineas a week, according to the room occupied; rooms with bathroom are from 21 guineas. The charges include all chemical, bacteriological, X-ray or other examination advised by the doctors, and all the usual forms of treatment, in addition to board and lodging. There are no extra charges except for alcohol (when ordered) and laundry. An examination and consultation fee of 15 guineas is charged on the first visit.

Address: THE SECRETARY, Ruthin Castle, North Wales.

Telegrams: Castle, Ruthin. Telephone: Ruthin 66

BOWDEN HOUSE.

HARROW-ON-THE-HILL.

For the residential treatment of Functional Nervous Disorders

No case under certificate nor under the M.T.A.

This home, which was founded in 1911, is designed to provide for psychoneurotics a curative environment associated with modern psychological treatment modified to suit each individual patient. The treatment is in the hands of three experienced psychotherapists, and most patients receive three hours of analytical treatment per week. Occupational therapy of many varieties is available but not obligatory. Recreations include tennis, badminton, billiards, etc.

On admission patients are examined by the diagnostic physician, who advises on all physical treatment. As far as possible all necessary pathological examinations are carried out by the pathologist in the laboratory on the premises.

STAFF:

H. CRICHTON-MILLER, M.A., M.D., M.R.C.P. (*Senior Physician*). GRACE H. NICOLLE, M.A., M.B. (*Resident Physician*).
 ALFRED TORRIE, M.A., M.B., Ch.B., D.P.M. (*Medical Superintendent*). MARY HALL, M.B., B.Ch. (*Pathologist*).

PROVIDES HIGHLY SUCCESSFUL
ORAL AND POSTAL COACHING FOR
ALL MEDICAL EXAMINATIONS

Special Preparations for all Surgical Qualifications.

F.R.C.S. ENGLAND. M.C. CANTAB.
(Primary & Final.) M.S. LONDON.
F.R.C.S. EDINBURGH.

And all other Surgical Degrees and Diplomas.

- 1. The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
- 2. Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
- 3. The Surgical Tutors of the College all hold either the M.S. Lond. or F.R.C.S. England, or both and are highly experienced teachers.
- 4. The Postal Courses are thoroughly clear, concise, and up to date and the test questions are carefully selected from those set at previous Examinations so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time and much unnecessary reading is saved.

Preliminary Examinations

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1

EXPERIENCED COACHING IN PHYSIOLOGY, Pathology, and Medicine, by M.D. Lond. (Hons.), M.R.C.P. Lond., B.Sc. Physiology Lond. All exams. Classes held.—Address, No. 7902, B.M.A. House, Tavistock Square, W.C.1.

THE ARMY DENTAL CORPS.

Applications are invited from DENTAL SURGEONS for appointment to commissions in the ARMY DENTAL CORPS.

Candidates, who should not be over 28 years of age, will for the present be selected for commissions without competitive examination, but will be required to present themselves in London for interview and physical examination. They must hold the degree or diploma of a British University or College of Surgeons and be registered under the Dentists' Acts or Medical Acts.

Successful candidates will, in the first instance, be given short service commissions for six years, at the end of which period they will retire with a gratuity of £1,000, unless they have been granted permanent commissions. Permanent commissions will be given to officers selected from among those who wish to make the Army their permanent career.

Particulars, including Regulations for Admission, pay and allowances, and forms of application may be obtained on request, either in writing or in person, to the Director, Army Dental Service, The War Office, London, S.W.1

THE INCORPORATED LIVERPOOL SCHOOL OF TROPICAL MEDICINE (University of Liverpool).

Applications are invited for the post of ASSISTANT LECTURER AND DEMONSTRATOR in the Department of Parasitology at the above School.

Candidates should be graduates of a British or Colonial university, and must hold a medical qualification or a good degree in zoology.

Initial salary £300-£400 (according to the selected candidate's qualifications).

Applications should be made not later than December 31st, 1938, to the Secretary, School of Tropical Medicine, Pembroke Place, Liverpool, 3, from whom further particulars may be obtained.

COACHING IN MEDICINE FOR ALL FINALs, by Physician, M.D., M.R.C.P. Recent successes. Personal tuition.—Address, No. 402, B.M.A. House, Tavistock Square, W.C.1.

MIDDLESBROUGH EDUCATION COMMITTEE

APPOINTMENT OF SENIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified men who have had experience of School Medical work, for the post of Senior Assistant School Medical Officer in connexion with the Medical Inspection and Treatment of School Children, and such other duties as may be required by the Education Committee. The person appointed will be responsible to the School Medical Officer.

Commencing salary £700 per annum, rising by annual increments of £25 to £750 per annum, thence by two annual increments of £50 to a maximum salary of £850 per annum.

The successful candidate will be required to devote his whole time to the duties of the office. The appointment will be subject to two calendar months' notice on either side, such notice dating from the last day of any calendar month.

Applicants must have had experience in the work of the School Medical Service and preference will be given to candidates who have had experience of Refraction work and who are recognized by the Board of Education in connexion with certification under the Mental Deficiency and Other Acts.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the successful candidate passing satisfactorily a medical examination.

Forms of application may be obtained from the Director of Education on receipt of a stamped addressed foolscap envelope, and these should be returned to the Director of Education, Education Offices, Middlesbrough, not later than Saturday, November 26th, 1938.

Candidates in any form will disqualify themselves. PRESTON KITCHEN, Middlesbrough Town Clerk.

November 7th, 1938.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF ANATOMY

Applications are invited for the whole-time post of SENIOR DEMONSTRATOR OF ANATOMY, to be received by the Dean of the Medical School on or before Saturday, November 26th, 1938.

Salary £400 per annum, with superannuation.

Appointments for Medical Officers in the **ROYAL AIR FORCE**

Medical men are invited to apply for Short Service Commissions in the Royal Air Force. Candidates must be registered under the Medical Acts and be not more than 31 years of age on entry.

The period of service is 3 years—extendible to 5 years. A gratuity of £400 or £1,000 is payable at the termination of 3 or 5 years respectively. Permanent commissions are awarded in a number of cases. These offer a pensionable career with the opportunity of extra leave on full pay for specialised study. Applicants who hold—or are likely to hold—post-graduate appointments in civil hospitals may, on joining the Royal Air Force, be seconded until the termination of their appointments (for a period not exceeding one year). An antedate of commission up to twelve months is allowed for appointments held at approved hospitals.

*Fuller information can be obtained from The Director
of Medical Services, Air Ministry, Kingsway, London.*

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in January, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list, and periods of unemployed or half pay are very rare. The assistance of private income is not necessary for the purpose of supplementing official pay and allowances.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than
November 21st, 1938.

RECRUITMENT OF EUROPEAN OFFICERS

Applications should reach the India Office as soon as possible.
INDIA OFFICE. NOVEMBER, 1938.

GENERAL POST OFFICE. HEADQUARTERS MEDICAL BRANCH (Male Staff)

There is a vacancy for a MALE ASSISTANT MEDICAL OFFICER in the Headquarters Medical Branch. The appointment is pensionable and carries a salary which commences at £500 a year, and rises by annual increments of £25 to a maximum of £800 a year. The rates of salary are liable to review.

Each candidate must be a fully qualified medical practitioner, a natural-born British subject and the child of a person who is or was at the time of birth a British subject. Preference will be given to candidates under 30 who have held one or more Hospital appointments. The successful candidate will not be allowed to engage in private practice in addition to his official duties.

Applications, stating qualifications, age, etc., with copies of any recent testimonials, should be sent to the Chief Medical Officer, General Post Office, London, E.C.1, not later than December 3rd, 1938.

Political influence should not be sought in support of applications; it would prejudice rather than assist the candidature.

The Male Medical Staff at Headquarters consists at present of a Chief Medical Officer, a Second Medical Officer and four Assistant Medical Officers. Information as to the duties can be obtained from the Chief Medical Officer.

Candidates may be required to attend for personal interview in London at their own expense.

HULL CORPORATION HEALTH DEPARTMENT

ANLBY ROAD INSTITUTION (HOSPITAL)
(580 Beds)

ASSISTANT MEDICAL OFFICER

Applications are invited for the above appointment from registered medical practitioners, of either sex, under the age of 40 years.

Salary £350 per annum, rising by annual increments of £25 to £450 per annum, together with an allowance at the rate of £150 per annum for board and residence outside the hospital.

The hospital is equipped with modern X-ray and Radium Departments.

The appointment will be designated under the Local Government and Other Officers' Superannuation Act 1922.

Applications, on forms to be obtained from the undersigned, are returnable not later than 10 a.m. on Monday, December 5th, 1938.

NICOLAS GEBBIE, M.D.,
Health Department, Medical Officer of Health,
Guildhall, Hull,
November 14th, 1938.

ST. MARYLBONE BOROUGH COUNCIL. APPOINTMENT OF TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH

Applications are invited from duly qualified and registered Medical Practitioners for the whole-time appointment of Tuberculosis Officer and Assistant Medical Officer of Health, at a salary of £800 per annum rising, on approved service, by annual increments of £25 to £1,000 per annum.

Candidates should not exceed 40 years of age.

Form of application and further particulars and conditions of appointment can be obtained from the Medical Officer of Health, Town Hall, St. Marylebone, W.1. Applications on the official form must be addressed to "The Town Clerk, Town Hall, St. Marylebone, W.1." and delivered in sealed envelopes marked "Tuberculosis Officer" not later than December 10th, 1938.

The appointment will be subject to satisfactory medical examination and production of birth certificate.

The Council's By-laws provide that canvassing shall disqualify an applicant.

WEST SUFFOLK COUNTY COUNCIL ASSISTANT COUNTY MEDICAL OFFICER AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited (from men only) for the above whole-time appointments, which includes duties in School Medical Inspection, Maternity and Child Welfare, Tuberculosis, Venereal Diseases, etc. Applicants must be registered Medical Practitioners and not exceed 35 years of age holding the Diploma in Public Health. Salary £500 per annum rising by annual increments of £25 to a maximum of £700 plus travelling allowance.

Particulars of appointment and forms of application may be obtained from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than December 5th, 1938. Canvassing in any form direct or indirect, will disqualify.

I. G. H. MUNSEY,
Shire Hall, Clerk of the County Council,
Bury St. Edmunds,
November 19th 1938.

COUNTY OF BRECON. ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of Assistant (male or female) Medical Officer for the County of Brecon, at a commencing salary of £500 per annum, rising by annual increments of £50 to a maximum of £700 per annum, with travelling and subsistence allowances according to the County Scale.

Applicants must be registered Medical Practitioners with at least three years' practical experience in their profession, competent to assist the County Medical Officer in the general administration of his Department, particularly in Ante-natal Clinic, Refraction work, examination of Blind Persons under the Blind Persons Acts, School Medical Inspection and Maternity and Child Welfare work, and must either possess special experience of practical midwifery and ante-natal work or have, prior to April 1st, 1930, held the appointment of Medical Officer of an Ante-natal Clinic with the approval of the Minister of Health.

Knowledge of Welsh desirable, and ability to drive a car essential.

The person appointed must be prepared to reside in or near to Brecon, will be under the direction of the County Medical Officer of Health, will be required to perform such duties as the Council may direct, and to devote the whole of his or her time to the duties.

The appointment will be terminable by three calendar months' notice on either side.

Canvassing members of the Council, either directly or indirectly, will be a disqualification.

The post is designated as an established post under the Local Government and Other Officers' Superannuation Act, 1922.

Applications must be made on forms which can be obtained from the undersigned, accompanied by copies of three recent testimonials, and must be received by me not later than November 25th, 1938.

W. F. W. BETENSON,
County Medical Officer of Health
County Health Office,
The Watton, Brecon
October 29th, 1938.

BOROUGH OF SALE. MEDICAL OFFICER OF HEALTH

The Council for the Borough of Sale invite applications from gentlemen holding the necessary qualifications for the position of Medical Officer of Health for their District.

The duties appertaining to the office will be, in all respects, those set out in Article 17 of the Sanitary Officers (Outside London) Regulations, 1935, and applicants should be registered in the Medical Register as holders of Diplomas in Sanitary Science, Public Health, or State Medicine.

The successful applicant will be required to devote the whole of his time to the duties of the office, which will include attendance at the County Child Welfare Centre, the fees in respect of which will be received by and paid into the funds of the Council; will be restricted from engaging in private practice, and will be required to enter into an agreement with the Corporation.

The inclusive salary will be at the rate of £800 per annum, rising by annual increments of £25 to a maximum of £900 per annum, together with a car allowance of £50 per annum.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, accompanied by copies of three recent testimonials, should be addressed to the undersigned, and should reach him not later than Monday, December 5th, 1938.

Town Hall, J. W. L. FOULKES,
Sale, Town Clerk.
November 15th, 1938.

CITY OF BIRMINGHAM. ASSISTANT MEDICAL OFFICER OF HEALTH.

The Public Health and Maternity and Child Welfare Committee invite applications for the post of whole-time Assistant Medical Officer of Health for general, and mainly administrative, public health duties. Candidates must be qualified medical practitioners and hold a Diploma in Public Health.

The successful candidate will be required to pass an approved medical examination, to contribute to the superannuation scheme, established under the Local Government and Other Officers' Superannuation Act, 1922, as amended by Section 82 of the Birmingham Corporation Act, 1935—Annuities for Widows—and, if under 30 years of age to join the Birmingham Municipal Officers' Widows and Orphans' Pensions Scheme.

The appointment will be terminable by one month's notice on either side. Salary £600 per annum, rising by £25 annually to £600.

Applications, endorsed "Assistant Medical Officer of Health and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, The Council House, Birmingham, 3, and returned to him by Saturday, November 26th, 1938.

Canvassing will disqualify.
F. H. C. WILTSHIRE,
Town Clerk.

COUNTY BOROUGH OF BARROW-IN-FURNESS

Applications are invited for the appointment of MEDICAL OFFICER OF HEALTH and FURTHER MEDICAL OFFICER of the Borough, subject to the provisions of the Sanitary Officers' Order, 1926 and the Local Government Act, 1933.

Candidates must not be more than 42 years of age.

The person appointed will be required to perform all the duties of a Medical Officer of Health under relevant Acts and Orders, to act as School Medical Officer for the Borough, Administrative Tuberculosis Officer, and Superintendent of the work of the Maternity and Child Welfare Service. He will also be required to act as Medical Superintendent of the Devonshire Road Isolation and Tuberculosis Hospital.

The person appointed must reside within the Borough, devote his whole time to the duties of the office, and not engage in private practice.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922. The successful candidate will be required to pass a medical examination.

The salary to cover all duties will commence at the rate of £900 per annum, rising, subject to satisfactory service, by annual increments of £50 to a maximum of £1,050 per annum. A motor-car allowance of £50 per annum will be granted.

Applications, endorsed "Medical Officer of Health," stating age, qualifications, and experience, and accompanied by copies of not more than three recent testimonials, should reach the undersigned not later than Wednesday, November 23rd, 1938.

Canvassing, directly or indirectly, is prohibited and will result in disqualification.

Town Hall, W. LAWRENCE ALLEN,
Barrow-in-Furness, Town Clerk

GUILDFORD RURAL, HAMBLEDON RURAL, AND HASLEMERE URBAN DISTRICT COUNCILS.

APPOINTMENT OF TEMPORARY ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered Medical Practitioners for the appointment as Temporary Assistant Medical Officer of Health to the Guildford Rural, Hambledon Rural, and Haslemere Urban District Councils.

The appointment will be for a period of six months only, and will be subject to one month's notice on either side at any time.

The salary will be £250 for the six months, plus £75 for this period for travelling expenses.

The duties of the appointment will be full time, and under the direction of the Medical Officer of Health. Such duties will consist of general Public Health duties, as well as assistance in first aid, and in assisting with the administration of the casualty services of the Air Raid Precaution Scheme.

Applications, stating qualifications and experience, accompanied by copies of three recent testimonials, should reach the undersigned not later than Wednesday, November 30th, 1938.

Preference will be given to candidates who have had previous experience in Public Health administration; and canvassing, directly or indirectly, will disqualify.

COUNTY COUNCIL OF DURHAM DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £400 per annum, rising by annual increments of £25 to £500 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered medical practitioner under the age of 50 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.

(2) He should have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(a) have had at least three years' experience in the practice of his profession,

(b) have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a hospital.

(3) He must be a medical officer in charge of beds occupied by either medical or surgical cases, and

(4) have received special training for a period of not less than six months in the diagnosis and treatment of tuberculosis.

(5) He will be attached to the County Health Department and will, subject to the direction of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

(6) He will be required to reside in his dispensary area, or such other area as required by the Council.

(7) He must be prepared, if called upon to act as locum tenens to other members of the medical staff of the County Medical Officer.

(8) The holding of a Diploma in Public Health will be deemed an additional qualification for the post.

The candidate appointed will be required to pass the County Council's medical examination and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," and accompanied by copies of not more than three recent testimonials, must be addressed to the County Medical Officer, Shire Hall, Durham, and must be received by him not later than first post on Monday, December 5th, 1938.

J. K. HOPE,
Clerk of the County Council.
Shire Hall, Durham.
November 14th, 1938.

LONDON COUNTY COUNCIL.

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

No charge is made to Principals for the introduction of Locum Tenens or Assistants

1. **BORDERS OF BUCKS AND BEDS.—PARTNERSHIP.—ONE-FIFTH SHARE.**—In common in old-established non-panel non-dispensing Practice. Receipts for last year £8,263, including appointments about £50 p.a. Suitable house on rental at £135 p.a., small garden, garage. Premium 2 years' purchase. Incoming partner should be experienced in anaesthetics and midwifery. Excellent sporting and educational facilities. Good hospital and all partners are on staff.
2. **ESSEX.—WITHIN 16 MILES OF LONDON.—PARTNERSHIP.—TWO-FIFTHS SHARE.**—After short preliminary assistantship in well-established good mixed-class Practice offering considerable scope. Receipts for past 12 months estimated to be about £2,500 p.a. Panel of 1,000. Fees 3/6 upwards. Choice of houses. Premium 2 years' purchase. Incoming partner must be experienced, especially in midwifery.
3. **DEVELOPING AREA WITHIN 12 MILES OF CHARING CROSS.—PARTNERSHIP.—ONE-THIRD SHARE.**—After short preliminary assistantship in better-class mainly private Practice established by vendor 7 years. Receipts for past 12 months £2,103. Selected panel of 300. Fees 3/6 to 15/-. Specially built house with excellent corner site (ample accommodation and garden, garage). Premium 2 years' purchase. Incoming partner should be about 30, married, and accustomed to better-class work. Ample scope.
4. **HERTS.—COUNTRY TOWN WITHIN EASY REACH OF LONDON.—PARTNERSHIP.—ONE-FIFTH SHARE.**—Increasing later (after preliminary assistantship) in very old-established rapidly increasing Practice. Gross cash receipts for past 3 years average about £3,500 p.a. Panel of 1,600. Appointments worth £360 p.a. Fees 2/6 to 21/-. Choice of houses. Premium 3 years' purchase. Incoming partner must be about 30, preferably married, and keen on midwifery.
5. **WEST OF ENGLAND.—MARKET TOWN.—Old-established PRACTICE** averaging for past 3 years £750 p.a. Appointments about £90 p.a. Panel of 600. Fees 2/6 upwards. Good house (ample accommodation and good professional rooms), large garden, garage. Premium for Practice and house £1,950, or near offer (mortgage can be arranged on house). Good hunting, shooting, fishing. Vendor retiring.
6. **LONDON, W.—Good-class non-panel, non-dispensing PRACTICE** offering scope. Average receipts for past 2 years about £600 p.a. Fees 7/6 to 21/-. Midwifery up to 30 gns. Suitable house in quiet residential district. Rent on lease £130 p.a. Premium 1 year's purchase.
7. **SHROPSHIRE.—Old-established unopposed mixed-class country PRACTICE.**—Receipts for past 3 years average £854 p.a. including appointments worth over £90 p.a. Panel of 460. Modern house with ample accommodation, electric light, garden, garage. Rent £80 p.a. Premium £950. Sport of all kinds.
8. **MIDLANDS.—LARGE TOWN.—PARTNERSHIP.—ONE-THIRD SHARE.**—Increasing to one-half (after short assistantship) in old-established mixed-class Practice, averaging for past 3 years £3,600 p.a. Panel of 3,755. Several appointments. Fees 2/6 to 21/-. Suitable house available. Premium 2 years' purchase.
9. **LADY DOCTOR'S PRACTICE.—OUTLYING EASTERN SUBURB.**—Receipts for past 3 years average £660 p.a. Panel of 247. Fees 2/6 upwards. Suitable house rented at £60 p.a. Offers invited.
10. **HANTS.—GOOD RESIDENTIAL DISTRICT NEAR NEW FOREST.—ONE-HALF SHARE.**—In well-established mixed-class Practice. Receipts average £2,500 p.a. Panel of 1,350. Appointments £273 p.a. Fees 3/6 to 21/-. Choice of houses. Premium 3 years' purchase. Incoming partner must be experienced and aged between 35-45.
11. **WEST OF ENGLAND.—COUNTRY TOWN.—PARTNERSHIP.—ONE-THIRD SHARE.**—(Increasing to one-half later) in very old-established middle-class Practice. Gross cash receipts for past 3 years average £3,000 p.a. Selected panel of 100. Fees 5/- upwards. Choice of houses. Premium 2 years' purchase. Good hospital in town and incoming partner (who should be about 30, married, and preferably hold a higher qualification) would probably be elected to staff. Sport of all kinds.
12. **DEATH VACANCY.—OUTLYING EASTERN SUBURB.**—Receipts for past 12 months stated to average £1,600, including panel of 1,600, and appointments worth about £100 p.a. Small house with garden, garage. Rent £104 p.a. Premium 2 years' purchase. Efficient locum in charge.
13. **S. WELSH COAST.—Old-established mixed-class PRACTICE.**—Held by vendor 18 years. Gross cash receipts for past 12 months £1,129, including Panel of 240 and various appointments. Fees from 3/6. Well situated house with ample accommodation. Small garden. Price £1,500. Premium 12 years' purchase. Sport of all kinds. Excellent educational facilities. Ample scope for man with higher qualification.

34. **NORTH WALES.—FAVOURITE COAST TOWN.—Better-class non-panel PRACTICE** averaging about £900 p.a. and offering good scope. Detached house excellently situated overlooking bay, with ample accommodation. Sport of all kinds and good educational facilities. Premium £1,400 for quick sale.
35. **MANCHESTER.—Very old-established middle- and working-class PRACTICE** averaging for last 3 years £1,330 p.a. Panel of £80 p.a. Appointments about £180 p.a. Fees from 3/6. House with 3 bedrooms, etc., garden, garage, electric light. Price freehold £950. Premium for quick sale, 12 years' purchase, part by instalments.
36. **LONDON, E.—Old-established mixed-class PRACTICE** averaging about £2,700 p.a., including panel of about 1,300, and increasing. Separate surgery premises. Premium 2 years' purchase.
37. **LONDON, N.W.—GROWING RESIDENTIAL DISTRICT.—PARTNERSHIP.**—Guaranteed share in rapidly expanding Practice producing to commence about £500 p.a., with increase later. Suitable detached house about £350 p.a. Incoming partner must be experienced and energetic.
38. **YORKS.—Country PRACTICE.**—Old-established, income about £1,030 p.a. with scope for increase. About £350 of present income is derived from panel of some 500 patients. Good freehold house with ample accommodation, garden and garage. Price for practice and house £3,600, of which about £1,900 may be left on mortgage.
39. **GLOS.—NORTH VALLEY.—Very sound PRACTICE** producing about £1,300 p.a. including panel of 1,150 patients and appointments worth about £50 p.a. Low expenses. Detached house with large garden, 5 bedrooms, etc. Freehold. Premium £2,200 purchase.
40. **FAVOURITE SOUTH COAST RESORT.—Private and better-class PRACTICE** averaging over £1,000 p.a. Minimum fee 5/-. No dispensing. Scope for man if desired. Modernized house with ample accommodation. Premium £1,000.

ASSISTANTS REQUIRED.—Several good vacancies. Full particulars on application.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

*a patient
convalescing
winter
on account
of
numol
will definitely
beat*

Convalescence is often prolonged by all manner of causes usually the result of weakened powers of assimilation. The patient needs some palatable, easily assimilable tonic that will build body and nerves speedily and lastingly.

For convalescents Numol is an ideal and unique prescription. It contains the various ingredients of a natural diet in the form required for rapid body-building.

Doctors are invited to write for a free jar.

NUMOL

THE BODY-BUILDING TONIC THAT DEFIES THE WINTER

TAVISTOCK SQUARE

TRADITIONAL LONDON

NORWICH HOUSE
ON OLD LONDON BRIDGE 1844

Old London Bridge stood some 200 feet eastward of the present bridge and consisted of 19 arches. Its entire length was lined with buildings including the famous Norwich House, an enormous pile four storeys high, with cupolas and turrets at each corner. It was brought from Holland and fastened together with wooden pegs instead of nails.

London Hospital Catgut has no less fine traditions behind its development to a leading place in the esteem of Surgeons the world over. It is a product of scientific research, made throughout at the London Hospital under licence of the Ministry of Health.

Postage 8d., Abroad 1s. 5d.

This standard work has long been unique as an encyclopaedia of reference for the general practitioner. To its wide and general use, sales of over 38,000 copies in the seven previous editions give ample testimony. The new edition has been thoroughly revised and brought up to date that it has the qualities of a new book. It has been entirely rewritten and reset in a new type and format. It remains a book to which the general practitioner can constantly refer for authoritative information on accepted therapeutic methods.

7 and 8, Henrietta Street, London, W.C.2.

The first two volumes in a new series
Cambridge Biological Studies
FORM AND CAUSALITY
IN EARLY DEVELOPMENT

64 text-figures.

By A. M. DALCQ.

12s. 6d. net.

Professor Dalcq discusses a selection of the data that, at the present time, appears to be most significant for a general comprehension of the ontogenetic problem. The book is of particular interest to the younger biologists, especially those who feel a vocation for research and are anxious to decide how best to direct their work.

THEORIES OF SENSATION

18 text-figures.

By A. F. RAWDON-SMITH.

10s. 6d. net.

This book describes in detail how it is now thought that our eyes and ears work, and, as far as possible, why these views are held in preference to others. It is written in the hope of interesting other biologists in the subject, and of stimulating further work, for which there is great need.

The second volume in

The Cambridge Library of Modern Science
BACKGROUND TO
MODERN SCIENCE

Edited by J. NEEDHAM and W. PAGEL.

7s. 6d. net.

Here, in one volume, is a complete survey of the development of science in the last forty years, each section being the work of an expert: Professor F. M. Cornford, Sir William Dampier, the late Lord Rutherford, Professor W. L. Bragg, Dr. F. W. Aston, Sir Arthur Eddington, Professor J. A. Ryle, the late Professor G. H. F. Nustall, Professor R. C. Punnett, and Professor J. B. S. Haldane.

HOW WE ASSIST IN THE PURCHASE OF MEDICAL PRACTICES

Scotland's Oldest Insurance Company is prepared to assist Doctors in the buying of Medical Practices or Partnerships. The purchase price is repayable over a term of years, and a Life Assurance Policy is taken out as a collateral security. This scheme makes it unnecessary for a Doctor to approach his friends to act as guarantors, and enables him to pay for his practice out of income. After the repayment of the Loan, the Life Policy becomes a valuable asset to the Doctor.

Many Doctors have already established themselves in practice with the aid of the "Caledonian" Scheme. The Interest Rates are particularly moderate. *The Accountant's charges for investigating the practice and the Legal Fees for preparation of the deeds and documents in connection with the Loan are paid by the Company in completed cases.* Arrangements can be made to meet special cases.

Full particulars on application to the Head Office, or to any of the Company's Branch Offices.

In waiting- rooms...

THERMOVENT

NATURAL CONVECTION ELECTRIC HEATING

provides a warm
healthy atmosphere
at a minimum cost

Heating for the waiting-room calls for convection-type heaters. Thermovent is the only compact and 100% efficient convector and, by virtue of its patented construction, it offers unique advantages:—

- ★ Thermovent warms and circulates the air, giving a pleasant, healthy atmosphere that visitors and patients will appreciate.
- ★ There is no radiation effect and no intense local heat—two feet or twelve feet away the warmth is the same. The element works at black heat—no charring of dust particles and no danger of scorching.
- ★ SPECIAL ELECTRICITY TARIFFS ARE AVAILABLE IN MANY AREAS FOR THERMOSTAT-CONTROLLED THERMOVENT HEATING.

There are inset, portable and floor-standing Thermovents in moulded or steel casings. All types available with built-in thermostat. Prices from £3.12.6. (1 kw). 2 kw and 3 kw types also available.

For full details write to—

THERMOVENT HEATING (Dept. D.M.3), E. K. COLE LTD., Southend-on-Sea.

Make a note of the number

THROMBIN-COAGULANT-MAW DRESSINGS

FOR THE RAPID CONTROL
OF HAEMORRHAGE

T.C.M. Dressings provide a new method of effectively and speedily controlling haemorrhage.

The Dressings are treated with Thrombin-Coagulant-Maw—a stable preparation of Thrombin, the natural clotting agent of blood—which anticipates the formation of Thrombin in normal shed blood and checks even severe haemorrhage within 5-15 seconds.

T.C.M. Dressings are not expensive, they cost, in fact, only a trifle more than ordinary Dressings, but one of these dressings will do the work of perhaps several ordinary dressings, thus proving cheaper in the end and saving you valuable time.

The Dressings are supplied sterile, in sealed drums, ready for use. The series consists of Wound Dressings, Lint Squares, and Lint and Plaster Dressings.

Thrombin-Coagulant-Maw is supplied also in Powder form.

SPENCER SUPPORTS ARE A DEFINITE HELP in DISPLACEMENTS of ABDOMINAL VISCERA

Spencer Supporting Corset shown open revealing inner abdominal supporting belt and its tapes which emerge outside the corset for purpose of adjustment. The pulling the lower tapes more snug than the upper ones distinct abdominal uplifters is attained. Note that the "pull" of support is placed on the pelvic girdle.

X-RAY A.—X-Ray of patient before her Spencer was adjusted. Note that stomach was dropped three inches below crest of hip bones represented by white dotted line.

X-RAY B.—X-Ray of patient after the Spencer abdominal support designed especially for her was adjusted. Note that the stomach is lifted to almost normal position.

The Spencer abdominal support you prescribe for a man or woman patient will be designed *Individually* to reach in under the abdomen and support the organs as nearly as possible in normal position, placing the weight of support on the pelvic girdle—NOT on the spine at or above the lumbar region.

Because it will be especially designed for the one patient who is to wear it AFTER many measurements and a description of the figure have been recorded, it will be securely anchored to the figure, so it will remain in place continuously and will not "give" or

stretch out of shape. Each Spencer is guaranteed to keep its exact shape up to the day it is worn out. It is the only support, to our knowledge, that carries this guarantee.

Special features are embodied in each Spencer which will improve posture, give back support and provide for adjustment of abdominal support at several different points.

Spencers are light in weight, flexible, easily laundered and comfortable. They are made of firm fabrics, not elastic, because fabrics are made to hold, whereas elastic is made to give.

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support a corset of another make has been substituted, and because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Spencer Supports and Corsets are never sold in shops.

May we send you this New Professional Booklet describing Spencer Supports and their Accepted Uses?

To establish a strong positive Iron Balance

Idozan contains 5 per cent. assimilable iron. It is non-constipating and acts in fact as a mild aperient. Idozan is a neutral solution, and exerts no harmful effect on the teeth. A tablespoonful three times a day provides the patient with a daily intake of 2.25 grams of pure iron, and thus establishes, without contra indications, a strong positive iron balance.

Idozan is now made in England, and is regularly prescribed by doctors in no less than fifteen different countries.

IDOZAN

The most extensively prescribed iron preparation in the World.

Packings: 4 oz., 8 oz., 40 oz., and 80 oz. bottles.

After Influenza Pneumonia and other Acute Infections

The general action of 'Bynin' Amara is manifested by increased tone of the nervous, muscular and cardiovascular systems. It stimulates the digestive organs, improves the flagging appetite, corrects anæmia and aids nutrition generally.

The marked asthenia and nervous depression which are prominent features of the post-influenzal state, yield rapidly to its influence. A course whenever there is any indication of lowered resistance is a valuable safeguard against infection.

HOW IMPORTANT ARE MINERALS IN THE DIET?

They are absolutely essential for the maintenance of an adequate state of nutrition. However, not infrequently an apparently minor mineral deficiency may weaken the body's defensive mechanism to such a point that

Pregnancy, Infection, or
any other unusual tax

may lead to a prolonged period of convalescence.

Prepared for the mouth and throat

'Dettolin' is specially made to kill quickly the micro-organisms concerned in affections of the mouth and throat. It contains, among other ingredients, the active germicidal principle of 'Dettol'—the modern antiseptic. For all its high germicidal efficiency, 'Dettolin' is soothing and gentle on delicate tissue. It has the added advantage of being distinctly pleasant to use, an important factor when frequent and regular gargling is prescribed.

'Dettolin' is obtainable from Chemists and Medical Suppliers.
Price 9d. and 1/3. Sample, and full information on request.

PRICE - 4/6 per 4 oz. bottle.

Sample and Literature on request.

Serenol is a sedative with action on the centres of the nervous vegetative system, sympathetic and parasympathetic, and on the cortical centres. Recent knowledge has shown the interaction of nervous vegetative system and endocrine system, and on this knowledge *SERENOL* is based. It is thus a biological, not a symptomatic, sedative, and, unlike many other sedatives, has not a direct depressant action on the cortical cerebral centres.

Serenol is indicated in conditions of anxiety and general irritability, insomnia, hyperthyroidism, hyperadrenalism (as in neurocirculatory asthenia, effort syndrome), the so-called nervous palpitations of the heart, etc.

Serenol is given in the following dosage. For mild cases one to two dessertspoonful on retiring. For more severe cases one dessertspoonful at 10 a.m., one dessertspoonful at 4 p.m. and two dessertspoonful on retiring.

Serenol, being a biological sedative containing no barbiturate, is not habit forming.

VEGETABLE PURÉES IN PEDIATRICS

A solution to the problem of home preparation

THE markedly improved nutrition and successful tolerance by infants to strained vegetables and fruits is rapidly securing a universal popularity for this dietary.

In theory there is no more desirable way of meeting systemic acidity, nutritional anaemia and supplying dietary bulk for intestinal residue in a non-irritant form.

In practice, however, defects in the home preparation of purées retard or defeat the end in view. The vegetables used are not fresh, overmuch water or boiling in uncovered kettles reduces the mineral and vitamin content, and coarse sieving allows harsh fibre to pass.

In consequence there is a growing demand on the part of physicians and mothers for such a product that shall have the highest possible nutritive value, and complete uniformity. Their attention having been drawn to this, the H. J. Heinz Company decided that here was a legitimate extension of their services in view of their wide buying resources and long experience in the preparation of foods.

This company is accustomed to buying vegetables in those regions where they grow best, and to dealing with them within a few hours of their harvesting at the correct season of the

year. This last is, of course, highly important.

The best factory practice is inevitably better than home preparation, however careful. After scrupulous cleaning, for example, vegetables are cooked in the Heinz factories under light steam pressure with exclusion of air until just soft enough to be comminuted by extrusion and cutting. The whole process is so regulated that the juices of the vegetables are retained throughout, there are no mechanical losses of mineral salts, vitamins or other soluble nutrients, and the resulting purée is adjusted to the proper consistency for satisfactory marketing.

Before filling and sealing, the product is subjected to a process for the removal of any absorbed air, and sealing takes place *in vacuo*. Finally, the sealed containers are immediately sterilised under known conditions of time and temperature. By these means are secured the high nutritional qualities, uniformity and convenience that physician, mother and patient desire.

NOTE.—Heinz Strained Foods are not packed in glass, for it has been found that light has an adverse action on vitamin content and palatability.

COMMON CONSTIPATION DURING PREGNANCY

How regularity can be maintained without aperients

IT is the experience of many leading obstetricians that, by increasing the intake of "bulk" in the diet, regularity can almost invariably be maintained throughout pregnancy without recourse to aperients.

For this reason, Kellogg's All-Bran is especially to be recommended in the diet of expectant mothers.

All-Bran is purified wheat bran in the form of an attractively crisp breakfast cereal. It provides the same type of fibrous bulk as that derived from fruit and vegetables but has this striking advantage: the fibrous matter in bran, unlike that of vegetables, breaks down less easily during the process of digestion and is therefore far more effective in promoting regular and thorough action of the bowels.

The function of All-Bran

The great value of All-Bran is that it absorbs water and softens like a sponge. This water-softened mass gently but effectively aids elimination. Eaten regularly, All-Bran promotes normal colonic peristalsis and results in easy, natural evacuation of the

bowel contents without strain on the pelvic organs. Moreover, its Vitamin B and iron content make it a particularly valuable food during pregnancy and lactation.

Eaten daily, All-Bran ensures comfortable regularity even during the later stages of pregnancy when the tendency to common constipation is increased by growing pressure on the internal organs. During the lying-in period it is also invaluable in aiding a quick return to normal habits and as a means of avoiding harmful strain on weakened muscles.

All-Bran may be served as a cereal with milk or cream, or cooked into appetising scones, bread, etc. It may also be taken in combination with other cereals or sprinkled over salads and other foods. To ensure maximum effectiveness, plenty of fluid should be taken, preferably between meals. All-Bran is obtainable from all reliable grocers. A packet will be sent free on request to any qualified practitioner. Inquiries should be addressed to: Kellogg Company of Great Britain Ltd., Stretford, Manchester.

An excellent breakfast for the expectant mother consists of All-Bran, with milk or cream, followed by fresh fruit or salad. To drink — weak, freshly-made tea, milky coffee or fruit juice.

MODERN COD LIVER OIL AS THE METHOD OF CHOICE FOR ADMINISTERING VITAMINS A and D

In view of the widely divergent opinions expressed concerning the dosage and vitamin content of various liver oils, the proprietors of 'SevenSeaS' cod liver oil wish to remind the medical profession that on January 1, 1936, the British Pharmacopoeia Commission laid down not only a definite dosage, but also a definite standard of vitamin content for cod liver oil.

The dosage was fixed at a minimum of 15 minims (a quarter teaspoonful) three times a day, and the vitamin content was standardised at not less than 600 International Units of Vitamin A and not less than 85 International Units of Vitamin D per gramme.

In 'SevenSeaS' Standard Oil, the practitioner has at hand a cod liver oil of the highest quality, fresh, easily digestible, and with a uniform vitamin content guaranteed to conform to the standard of the British Pharmacopoeia. The oil is rendered from the livers at sea as soon as the fish are caught (a process impossible with any other fish liver), instead of waiting until the ship is back in port and the livers consequently stale. The high quality of 'SevenSeaS' cod liver oil, and the uniformity of its vitamin content arising from its method of preparation, make it possible to prescribe only small doses which cannot give rise to acidosis.

These attributes are still further increased in the case of 'SevenSeaS' High Potency cod liver oil which is guaranteed to be four times as rich in vitamin values as the standard oil of the Pharmacopoeia. *With this oil available the practitioner who wishes to prescribe a particularly small dosage has the advantage of using a fresh cod liver oil without going far in excess of the standards laid down by the Pharmacopoeia regarding vitamin content.*

This High Potency Oil is not reinforced or in any way treated to increase the vitamin content. It is simply pure natural oil obtained by selection from the richest livers on the best fishing grounds.

All 'SevenSeaS' cod liver oil is tested and packed in strict conformity with British Pharmacopoeia requirements. Samples of the High Potency Oil, the Standard Oil, and the High Potency Oil in Capsules, will be supplied on request.

ANAHÆMIN B.D.H.

In the Treatment of Pernicious Anæmia

The administration of Anahæmin in pernicious anæmia has become a routine as a result of the uniformly satisfactory results produced.

Such results are exemplified in a recent report in which it is stated that weekly injections of 2 c.c. of Anahæmin for one month produced an increase in red blood corpuscles

from 536,000 to 3,700,000 and a rise in hæmoglobin from 25 per cent. to 60 per cent. At the end of a further six weeks' treatment it was found that the red blood count had risen to 4,600,000, and the hæmoglobin to 70 per cent. This increase in red blood cells from 536,000 to 4,600,000, was produced by a total dosage of 24 c.c. of Anahæmin.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

Measles Control with

IMMUNE GLOBULIN (HUMAN)

Lederle

BECAUSE of the frequency of complications, the mortality rate of measles is high - higher than that for whooping cough, diphtheria and scarlet fever.

Complications can be avoided by the use of IMMUNE GLOBULIN (HUMAN) *Lederle*, particularly those of broncho-pneumonia - responsible for about 50% of deaths in the infant age group (6 months to 3 years).

As a modification dose, one injection of 2 cc. is administered to patients in the infant age group from 6 to 8 days after exposure (for children in the same family this is 2 to 4 days after the appearance of rash in the exposing child). This dosage confers an active and lasting immunity in the majority of cases. For passive immunity of several weeks, a first dose of 2 cc. of IMMUNE GLOBULIN (HUMAN) *Lederle* is administered as soon as contact has been recognized; a second dose of 2 cc. four days later.

IMMUNE GLOBULIN (HUMAN) *Lederle* is distributed in 2 cc. vials and 10 cc. vials

THE COMPARATIVE VALUE OF ADULT SERUM, CONVALESCENT SERUM, AND IMMUNE GLOBULIN PATIENTS TREATED FOR PROTECTION OR MODIFICATION

ALL TYPES OF EXPOSURE

| Procedure | Cases | Per Cent. Protected | Per Cent. Modified | Per Cent. Failed |
|------------------------|-------|---------------------|--------------------|------------------|
| Adult Serum ... | 584 | 56.4 | 23.8 | 19.8 |
| Convalescent Serum ... | 1,627 | 75.4 | 16.8 | 7.8 |
| Immune Globulin ... | 1,341 | 71.5 | 23.9 | 4.6 |

The Lister Institute
OF PREVENTIVE MEDICINE

Compound Catarrhal Vaccine

In catarrhal conditions of the respiratory passages mixed infections are found more often than pure infections with one type of organism. *Bacillus influenzae*, *Pneumococcus* and *Micrococcus catarrhalis* are believed to be the commonest primarily infecting organisms, but *Streptococcus* and *Staphylococcus* seem to be responsible for many of the secondary infections. A mixed vaccine has been prepared from these five kinds of bacteria. It is generally given as a prophylactic, but may also be used in acute respiratory infections.

DOSAGE. Prophylaxis: 1st dose, 50 million *B. influenzae*, 10 million *Streptococcus*, 25 million *M. catarrhalis*, 25 million *Pneumococcus*, 125 million *Staphylococcus*. Subsequent doses at intervals of 7 to 10 days, gradually rising to 8 times the original dose. Then 4 to 8 times the initial dose every 4 to 6 weeks.

Treatment. $\frac{1}{2}$ to $\frac{1}{3}$ of the prophylactic doses.

PRICES. Ampoules containing

| | |
|--------------------------------------|-----|
| 235 million organisms per c.c., each | 2/6 |
| 470 " " " " " | 2/6 |
| 940 " " " " " | 2/6 |
| 1,880 " " " " " | 2/6 |

10 c.c. rubber-capped vials containing

| | |
|---|------|
| 470, 940 or 1880 million organisms per c.c., each | 15/- |
| 25 c.c. ditto ditto, each | 25/- |

Compound Influenza Vaccine

The Compound Influenza Vaccine prepared by the Lister Institute contains the chief types of bacteria found in the catarrhal secretions of the respiratory passages in epidemic influenza, viz. *B. influenzae*, *Pneumococcus*, and *Streptococcus*. It is primarily intended as a prophylactic, but may also be used for treatment.

DOSAGE. Prophylaxis: 1st Dose, *B. influenzae* 200 million, *Pneumococcus* 100 million, *Streptococcus* 50 million = 350 million organisms. 2nd Dose, 660 million organisms, 7 to 10 days later. In treatment 1st to 12th of the prophylactic doses may be given, commencing with the lower dose in severe cases.

Compound Influenza Vaccine

PRICES.

In ampoules of 1 c.c. containing 330 or 660 million organisms per c.c., each 2/6

In 10 c.c. rubber-capped vials containing 660 million organisms per c.c., 15/-
25 c.c. ditto ditto 25/-

"Vitamin B₁ deficiency an outstanding fault

In the diet of many millions of people"

THE LANCET, 15 Oct., 1937, p. 719

The reduction in Vitamin B₁ intake, due to changes in dietary habits during the last hundred years, normally amounts to at least 50 per cent., and may be as much as 75 per cent. It has been demonstrated, both experimentally and clinically, that a shortage of Vitamin B₁ acts as a limiting factor in the maintenance of health and nutrition, and often results in gastro-intestinal disorders, loss of appetite, indigestion, constipation and, if long continued, contributes to neuritis and arthritis.

The logical way to rectify such shortage is to restore to the diet the Vitamin B₁-containing substance whose removal is responsible for the deficiency.

This substance is available in the form of Bemax.

For years it has been the policy of the proprietors of Bemax to ensure its Vitamin B₁ activity by biological assay of every day's output. So far as is known, Bemax is the only food product for which such a claim is or can be made.

The quantity of Vitamin B₁ supplied by the normal daily dose of Bemax—one tablespoonful—is 20 International Units, an amount sufficient to raise a deficient diet to an optimal level.

The normal daily dose of Bemax supplies, in addition to Vitamin B₁, significant quantities of Vitamins B₂ and B₆, Copper, Iron and Phosphorus as well as rich quantities of Vitamin E and other essential dietary elements.

Bemax is an entirely natural product consisting only of stabilised wheat germs selected for their Vitamin B₁ activity with no addition whatsoever. Clinical sample and literature on request. Vitamins Ltd., (Dept. B.72), 23, Upper Mall, Hammersmith, W.6.

Habitual Abortion and Dietary Sterility

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

FERTITOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

A complimentary box of Fertitol Capsules and brochure sent on request.

CANCER OF THE BREAST*

BY

GORDON GORDON-TAYLOR, O.B.E., M.A., F.R.C.S.

Senior Surgeon, Middlesex Hospital

At the Annual Congress of the American College of Surgeons in 1932 one feature of the proceedings was a symposium entitled "Cancer is Curable," and large numbers of so-called "five-year cures" were forthcoming. The choice of subject on that occasion was avowedly propagandist, for it was strongly felt that until it could be brought right home to the laity that cancer is a curable disease early consultation and early treatment, so necessary for success, were not likely to be of frequent occurrence. Furthermore, those organizing that discussion fervently hoped, that the medical profession, and especially such as may have been depressed by an unfortunate series of cases, might be convinced anew of the real value of the various methods of cancer treatment in vogue, and would encourage their patients to avail themselves of these curative measures at the earliest moment. Doubtless similar motives actuated the officers of the Section of Surgery in their choice of mammary cancer as the theme for debate.

Some of you may have been privileged to attend the fourth Biennial Informal Conference of the British Empire Cancer Campaign in March, 1937, and have had the good fortune to listen to those apt, well-chosen words of Mr. Cecil Rowntree, who from the chair inaugurated the discussion on the "Present State of the Treatment of Cancer of the Breast": his participation in the affairs of this Section to-day recalls that successful meeting.

I am persuaded that in extending this invitation to me the Section is really desirous of obtaining such information concerning the end-results of the radical operation for cancer of the breast as may come from a surgeon who, save for a very brief period, has eschewed the methods of post-operative irradiation as a supplement to radical surgery in the cases of mammary carcinoma which are by common usage now classified as Group I and Group II. I have always regarded wide radical surgery as the method of election in almost every patient belonging to these two categories, but my debt to radiotherapeutic colleagues in respect of Group III cases, and of those patients with recurrent disease, is incalculable; I yield to none in my admiration for their humanity, enthusiasm, and optimism in their relations with a class of patient that is largely constituted by those condemned to die.

The methods of radiotherapy are indeed sometimes preferred by me in occasional cases of primary cancer of the breast: thus during the decade 1925-35 I employed, at Middlesex Hospital, radiation alone in thirty-nine cases of primary breast cancer, of which twenty-eight were Group III cases, eight belonged to the Group II class, and three were arranged in the Group I category. In the

advanced or "bad surgical risk" type of patient, three only are alive, the length of survival ranging from two to six years. Among these patients of this series who are now dead, one survived eight years and another succumbed only after five and a half years.

In another group of twenty-nine patients, in whom for various reasons a radical operation could not be performed, and who were submitted to a mere local removal of the breast, irradiation was superadded: only two survive, but of those patients now dead one lived ten years, one eight and a half years, and two others five and six years respectively. The patients who succumbed after eight and ten years died of maladies unconnected with the mammary carcinoma.

I have thus, for the most part, reserved radiation therapy for the advanced case or those unsuitable for radical surgery. It is with the results of the radical operation for cancer of the breast that I shall concern myself; and although I am conscious of a paucity of numbers I prefer to deal entirely with my own personal cases. These results are set out in the following table.

| | |
|--|-------------|
| Total cases of carcinoma of breast dealt with by radical operation from 1931 to 1935, inclusive | 693 |
| Cases untraced | 7 |
| Number of cases treated by radical operation up to 1935—that is, cases that could have survived 10 years or more | 353 |
| Group I cases operated on up to 1935 | 113 |
| Cases surviving 10 years | 95 (84.0%) |
| Group II cases operated on up to 1935 | 204 |
| Cases surviving 10 years | 60 (29.4%) |
| Group III cases operated on up to 1935 | 45 |
| Cases surviving 10 years | 3 (6.5%) |
| Number of cases treated by radical operation up to 1933—that is, cases that could have survived 5 years or more | 497 |
| Group I cases operated on up to 1933 | 163 |
| Cases surviving 5 years | 140 (85.8%) |
| Group II cases operated on up to 1933 | 233 |
| Cases surviving 5 years | 113 (49.0%) |
| Group III cases operated on up to 1933 | 51 |
| Cases surviving 5 years | 5 (9.8%) |
| Number of cases treated by radical operation up to 1935—that is, cases that could have survived 3 years or more | 551 |
| Group I cases operated on up to 1935 | 172 |
| Cases surviving 3 years | 147 (85.4%) |
| Group II cases operated on up to 1935 | 320 |
| Cases surviving 3 years | 159 (49.5%) |
| Group III cases operated on up to 1935 | 59 |
| Cases surviving 3 years | 6 (10.1%) |

Protracted Survival after Radical Mastectomy.—Of 158 patients who have survived radical mastectomy ten years or more, eight survived twenty-five years: six survived between twenty and twenty-five years†: thirty-three have lived between fifteen and twenty years: and 111 managed to attain a decade of years after their mastectomy.

Association with Carcinoma of Other Parts of Body.—Two patients have subsequently developed a primary carcinoma of the stomach: one twelve and a half years, one five years after mastectomy. Two patients have subsequently developed carcinoma of the rectum, each six years after mastectomy: two patients presented themselves with a simultaneous carcinoma of the rectum and

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Plymouth, 1938.

† These represent 1913 and 1914 cases. The war years furnish no statistics.

a carcinoma of the breast; both did badly and died of their rectal carcinoma. One patient survived an excision of the cheek, jaw, and floor of mouth ten years, and then developed a carcinoma of the breast; at the moment, two and a half years after mastectomy, she is alive and well.

Operative Mortality

There have been eight deaths in this series of 603 cases: one patient, inadvertently operated upon on the first day of her menstrual period, lost an inordinate amount of blood and died rapidly from the results of haemorrhage; another patient with diabetes, who had been under severe dietetic treatment before the days of insulin, died from exhaustion at the termination of the operation; one died of mesenteric thrombosis, one of erysipelas ten weeks after operation; one patient, where surgical removal was effected by diathermy, developed a wound infection with the Klebs-Loeffler bacillus, from which she succumbed; one with advanced heart disease died of heart failure, one from bronchopneumonia, and one of a pentine haemorrhage which took place during the operation.

The History of the Radical Operation

It is indeed appropriate that this discussion on cancer of the breast is being held in Plymouth, for this city cradled the "father of modern breast cancer surgery." Although cancer of the breast had been operated upon as far back as the Byzantine Period by Paul of Aegina, it was Charles Moore, born in Plymouth in 1821, and later surgeon to Middlesex Hospital, who in 1867 enunciated the necessity for removing, in addition to the entire breast, any unsound adjoining textures. Time does not permit me to do more than mention the names of Lister, Mitchell Banks of Liverpool, Gross of Philadelphia, Halsted of Baltimore, Harold Stiles and Heidenhain, Watson Cheyne, and my old master Alfred Pearce Gould.

The story of breast cancer would, of course, be incomplete without the name of my friend and colleague Sampson Handley, whose reputation in this sphere is international. These are the giants associated with the evolution of the radical operation for mammary cancer. Grey Turner first taught me the advisability of removing the clavicular head of the pectoralis major.

It was remarked by perhaps the wisest British surgeon of this century that where the ancillary methods of surgery are added to the knife in dealing with cancer the extent of the operative removal inevitably becomes curtailed; nor is it otherwise in the treatment of mammary cancer. Pre-operative and post-operative irradiation has gradually restricted the extent of surgical ablation; the curtailment is noted especially in the amount of skin removed, the clearance of the axilla, etc. By some, radium has even been regarded as the equal, if not the superior, of radical surgical removal. The figures produced by my friend Geoffrey Keynes are worthy of the closest study, and, emanating from the practice of so distinguished, experienced, and learned a surgeon, must command our earnest attention.

In order to secure some information as to the practice of other surgeons in respect of pre-operative and post-operative irradiation, I approached seventy-two of my friends throughout Great Britain, sending them the following questionnaire:

QUESTIONNAIRE ON CARCINOMA OF BREAST

1. For the ordinary "operable" cases of carcinoma of the breast (Stages 1 and 2 of the Geneva Convention) what is your usual treatment?

- (a) Radical mastectomy alone.
- (b) Operation plus radiation therapy.
- (c) Radiation therapy alone.

2. If the operation and radiation therapy—what form does this usually take?

3. Do you give pre-operative deep x-ray as a routine?

4. Do you give post-operative deep x-ray as a routine?

5. What treatment do you use for advanced cases (Stage 3 of the Geneva Convention)?

6. What treatment do you use for local recurrences? (Skin nodules, axilla, and supraclavicular triangle.)

7. Do you think that routine deep x-ray improves results of radical mastectomy? If you have any statistics readily available which prove this point or for the general results of your treatment of carcinoma of the breast would you add them below?

Unfortunately no very useful information for future guidance is forthcoming. Four different usages prevail: of the surgeons interrogated 25 per cent. make no use of irradiation as a supplement to radical operation; 44 per cent. use some form of irradiation in every radical mastectomy; 29 per cent. employ irradiation in Group II cases after radical mastectomy, and 2 per cent. favour the method of irradiation alone without radical removal.

The general tendency of surgical opinion is certainly towards the more frequent employment of supplementary irradiation, yet no figures warrant the constant and universal use of post-operative irradiation therapy as quoted by any observer. Some who employ post-operative irradiation have even naively stated that patients have confessed that the ordeal of irradiation is worse than radical operation.

I am not here to contrast one method of treating cancer of the breast with another, nor could I draw any fair conclusion as to their respective merits. A paper on prognosis in carcinoma of the breast, written by R. W. Searll and R. S. Handley (1938) concerns itself primarily with the evaluation of histological grading, but this has been employed in only a few of my cases. The histological points on which mammary tumours have been graded by Patey and Searll are:

1. Tubule formation; if well marked, this is favourable.
2. Pronounced irregularity in size and outline of nuclei; the greater the irregularity, the worse the prognosis.
3. The presence of hyperchromatic nuclei and of mitotic figures; the greater the number, the worse the prognosis.
4. The presence of secretion is regarded as favourable.

Little stress is laid upon other points, such as cell degeneration, infiltration by lymphocytes, or the appearance of the stroma.

Employing these criteria, Searll divided breast carcinomata into three grades of malignancy, but he does also admit that the presence or absence of axillary metastases is perhaps the most important single factor in prognosis, although this might seem an arbitrary standard by which to judge the clinical stage of the disease.

Where information is lacking as to the histological grade of the breast tumour no two series of cases or of treatments can be fairly compared. Apart from histological grading and the clinical stage of the disease the resisting power of the patient to cancer may also play an important part in prognosis; geographical environment may not be altogether negligible in determining the end-results.

Late Recurrences

It seems strange that cancer of the breast may recur as long as thirty-one years after the initial operation; Frank Steward (1925) records such a case operated upon

initially by Sir Henry Butlin, and mentions another of Sir Anthony Bowlby's. I have myself seen a carcinoma of the breast recur in the pelvis as a mass, the histological structure of which was reported as a "spheroidal-celled carcinoma of mammary type." The breast had been removed by Sir Cuthbert Wallace for carcinoma thirty years before. Three cases of recurrence in the scar have been observed by me twenty-one, twenty-two, and twenty-three years after operation by other surgeons. A case of my own developed a recurrence in the scar seventeen years after a radical operation, and this followed a few weeks after an acute attack of pyelonephritis, for which I had been called to treat the patient. I have seen local recurrence follow an operation for haemorrhoids performed sixteen years after the initial amputation; two recurrences followed gall-bladder operations, and one seemed consequent upon a hernia operation performed under a local anaesthetic six years after the mastectomy.

In most cases late recurrence has progressed disastrously, but exceptions are met with. One patient, operated upon for a mammary cancer seventeen years previously, developed a recurrence at the clavicular end of the scar. This was "flared" by radium, quickly becoming adherent to the clavicle; glands in the posterior triangle of the neck rapidly made their appearance, and there was increasing oedema of the arm. A "fore-quarter amputation" was performed, and the posterior triangle of the neck was cleared out at the same time. The patient survived two years, dying of metastases in the spine.

Certain geographical localities seem to "breed" a carcinoma of the breast of less malignant type: Mid-Hertfordshire has, in my experience, produced many ten-year and even twenty-year clinical "cures"; the Biggleswade and Sandy area of Bedfordshire seems conspicuous for the malignancy of cancers of all sorts.

Sure and accurate knowledge of the dread scourge will one day place in our hands some more specific cure than we at present possess, and much of the heroic in cancer surgery will pass into oblivion. In that golden era gross mechanical destruction of disease and cruel mutilation shall be no more, but even now much encouragement is to be found in the results of the surgery of breast cancer. A chaplain at "Middlesex" told me that during his three years' service at the hospital he had never met any patient who wanted to die. The addition of three years of life may not be always a trifling gift; five years' respite constitutes no paltry achievement; ten years may be a source of abiding joy to patient and relatives; twenty years spells a triumph!

Some may remember how the late Sir James Barrie, in his Rectorial address on "Courage" to the red-gowns of St. Andrews, reminded his listeners that "God gave us memory so that we might have roses in December." The memory of those 158 patients who have each survived more than ten years, perhaps many more years than ten, after an operation for a mortal disease like cancer of the breast, will be for me a reminder that I, too, can have my "roses in December."

It affords me great pleasure to acknowledge the kindly help of many friends. Miss Griffith and Miss Coysh of the follow-up department of Middlesex Hospital have furnished me with information about almost every single case of my own operated on in "Middlesex" since 1925; it is with pleasure that I express my sincere thanks to my registrar, Mr. A. S. Till, who pursues with tireless energy any research on which he is engaged. The courtesy and alacrity with which my questionnaires, sent to many friends, were answered and returned to me were perhaps not surprising, for British

surgeons are a "band of brothers." To the members of the medical profession whom I have assailed with letters I am under a great debt of obligation for the trouble they have taken to collect the information that I desired. To Miss Hall, my late secretary, I am grateful for aiding in the search for patients operated upon long ago. Miss Aspiotis had genius and pertinacity in obtaining news of patients operated upon even as long ago as thirty years. The topographical knowledge of my chauffeur, and many taxi-drivers, to say nothing of their enthusiasm, aided my efforts to secure the information I wanted. My own labours are also not undeserving of some eulogy when only seven cases have remained untraced.

TREATMENT OF PAIN IN THE FACE BY INTRAMEDULLARY TRACTOTOMY

BY

G. F. ROWBOTHAM, F.R.C.S.

(From the Neurosurgical Service of the Manchester
Royal Infirmary)

This paper is concerned with three cases of severe pain in the forehead which have been relieved by section, through the postero-lateral aspect of the medulla oblongata, of the pain fibres in the descending tract of the trigeminal nerve—a method recently suggested by Sjöqvist (1938) of Sweden.

The results of surgery in the relief of primary neuralgia of the face are outstandingly good, and, in fact, tic douloureux is one of the most gratifying ailments to treat in the whole realm of medicine and surgery. Important advances have been made since Horsley's description in 1891 of an unsuccessful attack on the sensory root of the trigeminal nerve several years before. It is to Hartley (1892) of America and Krause (1892) of Germany that chief credit must be given for the extradural approach through the middle fossa, which formed the basis of operative procedures destined to obtain so great a success. In the first instance both divided the trunks of the nerve distal to the ganglion, and it was not until a year later that Krause (1893) removed the ganglion itself. In 1901 Spiller and Frazier suggested division of the posterior root instead of removal of the ganglion, and it was this modification which so profoundly influenced all subsequent methods of treatment. Apart from conservation of the motor root, the great advantage of the method is that a fractional anatomical section is generally possible. Immediately behind the ganglion the nerve fibres run in groups corresponding fairly accurately with the three peripheral trunks, and can be isolated according to their relative positions, the mandibular and maxillary fibres occupying the lower and outer two-thirds of the root. Dandy (1929) claims that as the posterior root nears the pons varolii the fibres conducting the various modalities of sensation become rearranged into distinct physiological groups, so that by means of an intradural approach through the posterior fossa it is possible to divide only those fibres which are carrying pain impulses. It is doubtful whether this arrangement occurs in all cases, and there is much experimental evidence to disprove it. However, within the brain stem physiological grouping does take place, and in this position fractional physiological section is possible. Sjöqvist has devised a method by which he is able to divide the pain fibres in the descending limb of the trigeminal

tract by an incision through the postero-lateral aspect of the medulla oblongata, sparing the sensation of touch so that the face is not recognized by the patient as unpleasantly numb.

Case I

Intramedullary tractotomy for the relief of neuralgia in the ophthalmic division of the right trigeminal nerve.

History.—A woman aged 58 was admitted to the neuro-surgical service of the Manchester Royal Infirmary under the care of Mr. Geoffrey Jefferson. One day, nine months pre-

viously, when walking on the promenade at Blackpool, the wind "caught her face," and the next morning she experienced severe pain over the right eyebrow. The pain was essentially spasmodic in character; it came on in sharp knife-like stabs, starting in the eyebrow and shooting into the forehead. A spasm would be brought on by washing the face or by a cold draught, and in the past few weeks the pain had been almost intolerable.

On examination she was seen to be a small thin woman, though well preserved, and certainly not of the nervous or migmatic type. There was no loss of sensation in the face, and no abnormal neurological signs were found. It is rare for true *tic douloureux* to start in the ophthalmic division of the fifth nerve, but this was a genuine case.

Operation (performed by G. F. R., April 16, 1938).—Under avertin and gas-and-oxygen anaesthesia a wide cerebellar exposure was made through a transverse skin incision (Fig. 1). A generous amount of bone was removed, including the posterior margin of the foramen magnum, and the dura mater was opened through a Y-shaped incision. This exposed a large cisterna magna, filled with cerebrospinal fluid, and its release by puncture of the tough arachnoid membrane so lowered the tension in the posterior fossa that manipulations could be carried out with ease. The right cerebellar tonsil was retracted until the foramen of Magendie came into view; on lifting the cerebellar lobe still further the restiform body was exposed and at the side could be seen the roots of the vagus nerve, the curve of the vertebral artery, and the ascending root of the spinal accessory nerve. Two millimetres above the lowest vagal root and starting close to its origin from the medulla oblongata a transverse incision was

made into the right tuberculum cinereum in its outer part for a

FIG. 1.—Showing the site of the incision of intramedullary tractotomy.

FIG. 2.

FIG. 3.

FIG. 4.

FIG. 2.—Areas of sensory impairment present post-operatively in Case I.

Area 1: Complete anaesthesia, owing to the severance of the occipital nerves in the skin incision. Area 2: Pain sense is absent; thermal sense is faulty; light touch can be appreciated and accurately localized.

FIG. 3.—Areas in which sensory changes occurred post-operatively in Case II.

Area 1: Complete anaesthesia. Area 2: Pain sense is depressed; the corneal reflex is absent; thermal sense is faulty; sense of light touch is normal.

FIG. 4.—Areas in which sensory changes occurred post-operatively in Case III. Area 1: Complete anaesthesia. Area 2: Pain sense is absent; thermal sense has lost discrimination; light touch can be appreciated and correctly localized. The sensory changes in the lower part of the face are much lighter than over the forehead, and this is particularly so over the lower lip.

[NOTE: In all three cases sensation is normal on the opposite side of the face.]

tion of the cornea or haziness of the conjunctiva. Both eyes can be made to water freely. The tongue is analgesic on the right side in its anterior two-thirds, taste is present on this side, sense of smell is good in both nostrils, and all the muscles of mastication are active. There are no changes referable to the sympathetic nervous system—no pupillary changes, no differences in colour or temperature in the skin on the two sides of the scalp or face. This woman was an excellent witness.

Case II

Severe and persistent migrainous headaches treated by intramedullary tractotomy.

History.—A man aged 50 was transferred by Dr. Don from the medical wards to Mr. Jefferson's neurosurgical service on May 5, 1938. For fourteen years he had suffered from periodic headaches confined to the right side of the forehead. They would come on slowly, develop to a climax, and then slowly disappear. Occasionally specks would float before his eyes and he would feel sick. In the past ten days the headache had been continuous. Medical measures having failed, he was anxious to undergo any surgical treatment if there were a reasonable chance of gaining relief.

On examination he was observed to be a tall well-built man, and was living an active life as an overseer in a munition factory. He was of the nervous type, but not a single abnormal neurological sign was discovered. Migraine unassociated with any underlying pathological change was the obvious diagnosis. Because of the persistency and severity of the pain and the failure of ergotamine tartrate to give relief it was decided that surgical intervention was necessary.

Operation (performed by G. F. R., May 10, 1938).—The entrance was tedious because of massive nuchal muscles and a thick occipital bone. A good exposure was obtained, and a transverse incision 4 mm. long was made into the right tuberculum cinereum in its outer half just above the lowest vagal root, to a depth of 3.3 mm. Towards the end of the operation the pulse became irregular for a few minutes and extrasystoles developed. When the patient left the operating theatre his general condition was excellent: the right corneal reflex was absent and the left one was brisk. Within two days a "red" eye developed, but this was due probably to the trauma of repeated testing for the corneal reflex rather than to paralytic interstitial keratitis, and it cleared up in forty-eight hours. During convalescence he had a little difficulty in swallowing: this was subjective rather than objective. There was a fine nystagmus on lateral fixation to both sides; no cerebellar signs were present in the arms or legs.

Fig. 3 illustrates the areas in which sensory changes occurred post-operatively. Area 1 is completely anaesthetic, due to severance of the occipital nerves in the skin incision. In the right side of the face and forehead the sensation of pin-prick is dulled, the analgesia fading in density from above downwards. Thermal sense is not so discriminative as in the corresponding areas on the left side. Light touch is present and can be localized perfectly.

In this case the tracts had been bruised rather than severed completely, because, as the days went on, the analgesia began to fade from below upwards. This is an important observation, since it shows that a fixed length or depth of section is not entirely adequate and that each case must be judged individually. This man had a bulky and very wide medulla oblongata, and so the medullary incision would have been better lengthened and deepened.

Case III

Intramedullary tractotomy for primary neuralgia affecting the ophthalmic division of the left trigeminal nerve.

History.—A man aged 56 was admitted to the neurosurgical service of the Manchester Royal Infirmary, under the care of Mr. Geoffrey Jefferson, complaining of pains in the left forehead. These started in November, 1935, and had appeared at intervals ever since, the last attack being very persistent. When he appeared at the out-patient department he was

suffering from severe pains—so severe, in fact, that he refused to go home, and insisted on being admitted to the hospital as an urgency. The pain started in the region of the supra-orbital notch and, in spasms, shot upwards into the forehead as if red-hot needles were being driven into the skin. Each spasm would last a second or so, and then the pain would disappear, to be repeated in about a minute. In the past four days the intervals of relief had been so short that he was almost demented.

On examination there was not a single abnormal neurological sign and, in particular, no sensory loss in the face. It is unusual for true primary major neuralgia to start in the ophthalmic division of the trigeminal nerve, but this was a typical example.

Operation (performed by G. F. R., May 21, 1938).—In this case the experience gained in the two previous operations permitted a more limited exposure of the posterior fossa, and a low mid-line entrance was made. At the level of the lower fibres of the vagal line, and starting at their superficial origin, a transverse incision 4 mm. long and 3.5 mm. deep was made into the left tuberculum cinereum. The incision had to be performed in two cuts because of a large vessel which ran vertically across the proposed line of section and could not be mobilized. At the end of the operation the patient was in excellent condition: the left corneal reflex was absent, whereas the right one was brisk. The next day his left arm was wildly ataxic, the left leg a little unsteady, and there was a fine rapid nystagmus on lateral fixation; but all these signs disappeared in three days' time. General convalescence was easy and smooth throughout. For a few days there was some difficulty in swallowing, which again was subjective rather than objective, and difficulty in micturition which did not necessitate catheterization.

Fig. 4 illustrates the sensory changes which occurred in the face post-operatively. The anaesthetic area at the back of the scalp is due to severance of the occipital nerves in the skin incision. Area 2 is analgesic, thermal sense is depressed, a hot test-tube being appreciated as a warm one, and a cold tube as a little less warm than the hot one. Light touch can be appreciated and correctly localized. The man volunteered the statement that the sensory changes were "heaviest" from above downwards. He has had no neuralgic pains since the operation, and is now a much happier-looking man.

Commentary

The immediate relief of severe forehead pains in three cases has been conspicuous, and though not enough time has yet passed to allow of a final evaluation of the method in the therapeutics of neuralgias the nature of the operation suggests that the good results will be lasting.

The advantages of the method are that the face is not completely denervated; analgesia is densest in the forehead, and the muscles of mastication are never paralysed—an important consideration, as bilateral neuralgia is by no means uncommon. Moreover, the great superficial petrosal nerve (nerve of tear-secretion) is far from possible injury, and so a dry eye is avoided. It is the loss of tear-secretion which is thought to be the main factor in the production of corneal "steaming" or ulceration, a troublesome complication occasionally following posterior root section.

The operation also makes an interesting neuro-anatomical experiment in elucidating the destination of the fibres in the posterior trigeminal root. Somatically, the face is represented upside down in the long spinal nucleus and the vascular lesions of the brain stem, and in particular the occlusions of the posterior cerebellar artery have often shown a dissociated sensory loss, pain sense being absent and touch intact. The Sjöqvist sections furnish, for the first time, experimental proof in the human that fibres conveying the various modalities of sensation are rearranged within the brain stem into physio-

logical groups, the pain fibres probably having the lowest and the touch fibres the highest representation in the somatic sensory nucleus of the trigeminal nerve.

THE EMPLOYMENT OF DIABETICS

BY

R. D. LAWRENCE, M.D., F.R.C.P.

AND

KATE MADDERS, M.B., B.S.

(From the Diabetic Department, King's College Hospital)

Diabetics still suffer great difficulties in their work and employment from the public misapprehension that they are necessarily invalids. However fit and healthy he or she may be under appropriate treatment, the patient with diabetes cannot enter any Governmental or similar service, is barred from all types of employment which are pensionable, and is liable to find himself discharged when his private employer knows of his disease. As a result, patients with diabetes must often hide their condition and miss necessary visits to our day clinics (we now have an evening clinic for them), as these might disclose the disease to their employers. Young diabetics entering industry are rarely accepted by an approved society, and can usually only get health insurance through the Post Office scheme, with its limited benefits. Many children, after winning scholarships for higher education, find that they cannot take them up because they suffer from diabetes. Altogether, many lose confidence from rebuffs in finding the type of work they wish to do and which they are most capable of doing well.

From experience with our hospital clinic we consider the above attitude quite unjustified, unfair, and a mere survival of pre-insulin days, when ill-health—that is, industrial inefficiency—and early death were the rule. Patients appeal to us and to the Diabetic Association, which concerns itself with such difficulties, to help them against this injustice and handicap. The Diabetic Association suggested that an investigation should be made of the employment efficiency or disability in our hospital patients so as to produce facts instead of vague impressions. The results of the inquiry follow.

Investigation in a Hundred Cases

No special selection of employed patients was made, but the first 100 employees attending the clinic were studied. As most of these patients attend at intervals of

about three months it took about six months to investigate 100 cases. Both sexes were included, but the majority (75 per cent.) were men. Their ages varied from 14 to 65, but 73 per cent. were under 40 years old and consequently cases of severe diabetes; the majority (83 per cent.) were having insulin treatment continuously. The average amount of insulin given was 35 units, and varied from 80 to 8 units daily. The duration of employment as diabetics varied from one to nineteen years, with an average of five years. All types of employment—some strenuous, some sedentary—were found, and included such occupations as gardening, engineering, carpentry, commercial travelling, shopkeeping, office work, work as telephonist, domestic service, etc.

It is realized that the data obtained are inaccurate, since patients chiefly depend on their memory. In every case, however, we have checked their story from attendance records and found it to be reasonably accurate. The tendency was to remember "diabetic illness" but to forget minor indispositions—influenza, colds, etc.—which, however, were usually noted in the case records. It was soon recognized that it was necessary, in observing the effects of diabetes *per se* on time lost in employment, to distinguish between diabetic illnesses directly due to the disease and fortuitous illnesses: febrile colds, appendicitis, etc.—that is, common illnesses not caused by diabetes. Again, it was thought right to distinguish between the time lost at the onset of diabetes, while treatment was being worked out, and after restoration of health by adequate treatment. We have not included visits to our clinic (on the average four half-days a year) as time lost! The figures have therefore been prepared in the following way:

Loss of Working Time in 100 Diabetic Cases

For Diabetic Illness:

| | Cases |
|--|-------|
| I. No loss of time, even at onset | 39 |
| II. Time lost at onset only | 38 |
| | 77 |
| III. Time lost after first stabilization | 23 |
| | 100 |

Analysis of Group III:

| | Cases |
|---|-------|
| Restabilization necessary in cases with good health on diet for 1-3 years but which broke down and needed insulin | 8 |
| *Sepsis (carbuncles, ulcers of foot, etc.) | 5 |
| Diabetic coma | 2 |
| Hypoglycaemia and after-effects | 4 |
| *Neuritis | 2 |
| Cataract (after 11 years' work as diabetic) | 1 |
| *Hyperthyroidism | 1 |
| | 23 |

* It is doubtful if some of these conditions should be classed as diabetic illnesses.

For non-diabetic Reasons, time was lost by 55

Their illnesses included bronchitis, influenza, appendicitis, accidents, and, of course, colds, bilious attacks, etc.

It was hoped at first to get accurate figures of the days or weeks lost for the above reasons, but this was found impossible. We are sure, however, that our patients were not longer incapacitated from work by influenza, accidents, and so on, than non-diabetic individuals.

The school attendances of children have not been included in this survey, but the matter is being investigated. The result ought to be interesting: the figures will be more accurate, since they can be checked, and will allow of comparison between groups similar in all respects except their diabetic diathesis.

Conclusions

A survey of 100 employed diabetics shows that 77 per cent. lost no time from work because of their diabetes after the initial stabilization of treatment, and the figure is 85 per cent. if the ultimate stabilization on insulin of another 8 per cent. originally treated by diet alone is included; 55 per cent. lost some time from illnesses unconnected with their diabetes. Our survey has no statistical accuracy; even if it had there seem to be no figures available to compare the working time lost by our patients with that lost by a mixed non-diabetic population. We think, however, the survey shows that most treated diabetics are good employees from the health point of view, and hope that the widespread prejudice against their employment may be removed. In addition it should be pointed out that we have surveyed only the hospital section of the working community and that we know that the work loss of a higher stratum of diabetics, whose incentive to work is usually greater, is still less.

We wish to thank the Halley Stewart Trust for grants to our department to provide funds for such social studies.

ACUTE BULBAR PARALYSIS

REPORT OF TWO CASES

BY

D. M. ANDERSON, M.B., Ch.B.

AND

J. H. DIXON, M.B., B.Chir.

The cases described below present features of sufficiently unusual interest to justify their publication. First, the syndrome was identical in both instances, the bulbar condition being the only paralytic manifestation; and, secondly, both patients died twelve days after tonsillectomy.

Case I

This patient was a female child, aged 6 years, of a small and somewhat frail physique. On July 25 she had her tonsils removed by guillotine. She was seen again on the 29th, when she complained of frontal headache, earache, and slight pyrexia. There was a history of a previously restless night with sudden starting up in fright. In view of the local prevalence of poliomyelitis a routine examination of the nervous system was made, but no evidence of any nervous lesion could be found. The tonsil beds were healthy and granulating. There was no sign of congestion of the drumheads, nor was there any tenderness over the mastoid cells.

The following morning the temperature was normal and the headache was gone, but there were still shooting pains in the ears, with no deafness or signs of otitis. Two days later she was well and wanted to get up. She remained well until August 5, when there was a return of the headache with pyrexia of 99.5° F. The next morning the headache had gone, but the temperature had risen to 103° F. Thick mucus was present in the throat that was difficult to remove; she could not be persuaded to cough it up or to swallow it. She was able to swallow fluids in small quantities, but in a way that suggested the presence of some obstruction in the throat. On examination the throat appeared healthy, but the palate on the right side seemed to be lower. There was no sign of pharyngeal congestion, and the tonsil beds had quite healed. There was a copious amount of thick mucus which made examination difficult, but its removal by a swab was not unduly resented. The child did not look ill, nor did she complain of any pain or discomfort. Constipation was stubborn. During the course of the day the amount of

secretion in the throat increased to a degree which became alarming, and it seemed to threaten to choke her. At this stage a very transient drooping of the right side of the face was noticed on momentary occasions. She developed a wild look, and tried to strike out at anyone who was beside her; she was continually turning from one side to the other and occasionally leapt up in bed; she gave the impression of being enraged at her inability to remove the mucus, for she was able to speak and was quite rational. At this stage the temperature was still 103° F., and the pulse was 110. The only signs in the lungs were a few moist sounds at the bases. The respiratory rate was 22. She was given 100 grain of atropine to diminish the secretion, after which she appeared to quiet down and was able to snatch sleep at ten-minute intervals, when the mucus woke her again. The pulse rate did not rise in spite of the atropine.

During the early hours of the morning her condition became worse; the lungs became congested, the pulse rate rose to be uncountable, and the temperature began to fall. There was no attempt at coughing, and the secretion in the throat disappeared while the oedema of the lungs progressed with increasing cyanosis. The soft palate of the right side was much lower than that of the other side. The pupils were small and did not react to light. Towards the end there was a persistent pouting appearance of the lips which was quite symmetrical; she was able to speak, but in a muffled manner. Towards the end she repeatedly asked for drinks, which were mostly regurgitated through the nose.

The congestion and the cyanosis increased and some head retraction was evident. She died about fifteen hours after the first appearance of the acute dysphagia. At no time during the course of the disease was there any disturbance of the nervous reflexes or the muscle tone, with the exception of the terminal head retraction. She was conscious until she died, and was able to understand questions and to reply, although indistinctly.

Post-mortem Findings.—The lungs were oedematous, with several small haemorrhagic infarctions present, probably terminal. The heart muscle appeared healthy, but there was some dilatation of the right side. An excess of free fluid was present in the pericardium. Examination of the brain showed that the pia mater was markedly hyperaemic without any exudate. On section through the medulla the grey matter appeared hyperaemic and bulged. The spinal cord showed no macroscopic change.

Case II

A robust female child, aged 14 years, had her tonsils removed on July 25 on account of a tuberculous adenitis. She made an uneventful recovery from the operation, and was out in the fields a week later. The patient was seen again on the evening of August 6; she gave a history of having been out of sorts for the past two days, which was attributed to the strong sunshine. On examination she was found to have a temperature of 101° F., and, when asked, admitted that she had a slight headache. There was no neck rigidity, and Kernig's sign was negative; abdominal reflexes were active. The bowels had not acted for three days. On the following morning the temperature had risen to 103° F., and the headache was still present though not severe. The pulse rate had dropped to 80 and the respiratory rate was 20. There was a complaint of a thickness in the throat and a difficulty in raising the phlegm. The throat appeared perfectly healthy and symmetrical, and the tonsil beds had healed up. A throat swab was taken, and the report later stated that no streptococci, haemolytic or non-haemolytic, were present. Examination of the chest failed to reveal any abnormal signs. Later in the day there did not appear to be much change except that the secretion was more copious. The pulse rate was still slow in proportion to the temperature. An hour and a half later the child was seen again. She was then teaping up in bed and flinging her arms about, with a wild look in her eyes. Her temperature was subnormal and the pulse was uncountable; the pupils were dilated. During examination she projected a copious quantity of stomach contents all over the bed. Following this a transient drooping of the

right side of the mouth was noticed, which disappeared as she moved. Shortly after a large quantity of strawberry-coloured froth welled up from the mouth; the child was still fully conscious, but, although making attempts, she was unable to speak. The restlessness was severe, but she settled slightly after morphine and atropine, but died half an hour later. It appeared that half an hour before she was last seen she had asked for something to eat and was given some milk mixture; she had taken this quite well and asked for the back rest to be lowered so that she could go to sleep. Apparently this was done, and was followed a few minutes later by the alarming symptoms described above. In short, she had appeared reasonably comfortable at 9 p.m. and was dead at 11 p.m.

Post-mortem Findings.—The lungs were markedly oedematous; the heart was somewhat dilated, with no free fluid in the pericardium, while the musculature appeared healthy. The brain and spinal cord gave no macroscopic evidence of congestion. Apart from slight enlargement and softening of the spleen there were no visible changes suggestive of any toxic process.

Both cases were given prontosil from the onset.

Discussion

There is a remarkable similarity in the course of the above two cases, and a discussion of their features appears to resolve itself into three definite stages: (1) the stage of invasion; (2) a stage of irritation; and (3) a stage of rapidly progressive paralysis.

1. *The Stage of Invasion.*—In the first case the symptoms were headache and possibly earache, accompanied by slight pyrexia that settled down in twenty-four hours and was followed by a period of comparative well-being. In the second case there was no headache, but the patient complained of feeling out of sorts.

2. *The Stage of Irritation.*—This stage is considered to begin with the return of the pyrexia and the headache. The first unusual symptom was the appearance of sticky mucus in the throat that was difficult to swallow. This mucus probably originated from the submaxillary and sublingual glands, and might be considered to be due to increased activity of the secretomotor fibres of the vagus which arise in one of the dorsal nuclei and are referred to by Samson Wright as the superior salivary nucleus. A pulse rate slow in proportion to the temperature was also found in both cases at this stage, due in all probability to stimulation of the depressor fibres of the vagus. A further common feature was obstinate constipation. It is apparent that all the symptoms of this stage can be attributed to vagal stimulation, which is considered to have been produced by toxic irritation of the dorsal nuclei in the medulla before the actual changes that later produced paralysis. No actual paralysis was demonstrable, and the difficulty in swallowing was attributable to the presence of the thick mucus, which could be swallowed only with an effort; fluids could be taken without much difficulty, and there was no regurgitation until later.

3. *The Stage of Progressive Medullary Involvement.*—The onset of this stage was fairly sudden in both instances. It was ushered in by episodes of explosive muscular activity in association with a wild appearance of the eyes. The temperature dropped and the pulse rate rose rapidly. Signs of pulmonary congestion became increasingly prominent, although there was no evidence of respiratory failure at any time. The mucus disappeared from the throat, and a right-sided paralysis of the soft palate was seen in one case. Transient right-sided facial paralysis was present in both instances. Ability to swallow was also impaired; later it was complete, with regurgitation

of food through the nose. Speaking was muffled, yet consciousness remained. The terminal event was pulmonary oedema, more acute in the second case. At this stage the prominent symptoms were associated with progressive impairment and ultimate destruction of vagal control, both motor and sensory. Here a short description of the relations in the medulla seems pertinent. The ascending fibres of the seventh, ninth, and tenth cranial nerves end in a column of dorsal nuclei from which the involuntary fibres arise. Descending fibres end in the grey matter just lateral to that column in the fasciculus solitarius. The voluntary fibres of the seventh, ninth, tenth, and eleventh cranial nerves arise in one column just anterior and lateral to the dorsal column and extend from the lower border of the pons through the medulla to the spinal cord. The former column may be taken to correspond to the posterior horn cells and the latter to the anterior horn cells of the spinal cord.

The rapid pulse, the disappearance of the mucus from the throat, the progressive paralysis of the soft palate and the muscles of swallowing, and the signs of cardiac failure are clinical evidence of damage in the region of the dorsal columns. The pulmonary oedema was probably secondary to ventricular failure from loss of vagal control. The presence of transient facial paralysis at the end suggests that the lesion was spreading upwards. Furthermore, the terminal wild appearance and choreic movements might have been produced from irritation in the region of the red nucleus and thalamus.

Only in the first case was there any sign of meningeal irritation as indicated by the terminal head retraction, and post-mortem evidence of meningeal congestion was found only in this case. Here also there was constriction of the pupils with loss of reaction to light, suggesting third-nerve involvement. Extreme dilatation was apparent in the other case, possibly from sympathetic over-excitation by loss of vagal inhibition. Therefore, clinically, it appears that the seventh, ninth, and tenth cranial nerves were affected, while the close anatomical relationship of their nuclei in the medulla can leave little room for doubt as to the site of the major lesion. First the dorsal column corresponding to the posterior horn cells was affected and later the motor column, corresponding to the anterior horn cells. This is the usual sequence of events when the spinal cord is affected by the virus of acute anterior poliomyelitis.

The most striking feature of the above two cases is the fact that both patients died twelve days after tonsillectomy. It is perhaps permissible to suggest that they died from the virus which causes acute anterior poliomyelitis, especially since the disease occurs in the district in epidemic form. At present the disease is supposed to be due to a filterable virus which gains entry via the nasal mucous membrane. The path of invasion is apparently through the peripheral nerve terminals in that mucous membrane. It is highly probable that the virus entered through the raw tonsil bed to produce a specialized form of the disease. The tonsil area of the throat is innervated by the glosso-pharyngeal, and the infection travelled up the peripheral nerve to produce the damage in the region of the dorsal nuclei from which the glosso-pharyngeal arises. These children made contact with one another only for a short time after the operation; they lived a considerable distance apart, and had not been in contact with known cases of the disease. Two other children who were operated on at the same time are at present well.

Portions of the brain and spinal cord are being cultured, and diagnosis has yet to be confirmed by injection of brain

substance into monkeys. Since this will take some time it was considered advisable to report these cases while the disease was still prevalent.

Summary and Conclusions

1. That these are cases of polio-encephalitis.
2. That there is a definite association between the course of the disease and the presence of a raw tonsil bed, even although it was completely healed up when the symptoms of the disease arrived.
3. That the incubation period in these cases was about four days, presuming that the infection took place at the time of tonsillectomy.
4. That the route of the infection was from the raw tonsil bed to the dorsal nuclei via the peripheral fibres of the glosso-pharyngeal nerve.

HAEMORRHAGE FOLLOWING TONSILLECTOMY

BY

D. W. ASHCROFT, D.L.O., F.R.C.S.

Otological Registrar, Middlesex Hospital

The purpose of this paper is to discuss a subject which is of the utmost importance not only to all oto-rhino-laryngologists but to all surgeons, house-surgeons, and general practitioners who may be faced with the problem of haemorrhage following tonsillectomy. It is a very real problem and one, moreover, to which only scanty reference is made in even the largest and most authoritative of textbooks. Such haemorrhage is terrifying enough for the patient, and may be even more alarming for the medical man unaccustomed to dealing with such cases.

For the efficient treatment of haemorrhage following tonsillectomy a thorough knowledge of the factors concerned in its production is necessary, and careful consideration of these factors will do much to minimize the occurrence of this distressing complication. I propose to discuss this subject under the following headings:

I. *Factors influencing the occurrence of haemorrhage following tonsillectomy:* (a) pre-operative; (b) operative; (c) post-operative.

II. *Types of post-operative haemorrhage.*

III. *The management of a case of haemorrhage following tonsillectomy.*

FACTORS INFLUENCING ITS OCCURRENCE

Pre-operative

Although tonsillectomy may be indicated in any particular patient, certain precautions must be taken before operation is decided upon, and many factors remain to be considered before the actual time of operation is arranged. In taking a history of the case and during examination of the patient particular attention should be paid to the following points.

1. *Severe Tonsillitis or Peritonsillar Abscess.*—Recent acute local infections increase the risk of haemorrhage both during and after operation, and for this reason tonsillectomy should not be performed within a period of a few weeks following either of the above conditions. No hard-and-fast rule can be laid down as to the time which should be allowed to elapse before operation is undertaken, but I am of the opinion that, following such acute local infections, tonsillectomy should be

deferred for a period of not less than four weeks in the case of children and not less than six weeks in the case of adults.

*2. *Infections of the Nose or Nasal Accessory Sinuses.*—Acute sinusitis, whether associated with a sore throat or not, is a contraindication to the immediate performance of the operation. A common cold comes under the same category. The presence of chronic sinusitis should not be overlooked. Adequate measures for its efficient treatment should be instituted before tonsillectomy is considered.

3. *Bleeding.*—Inquiry should be made as to whether there is any susceptibility to bleeding on the part of either the patient or any member of his family. The occurrence of prolonged haemorrhage following cuts or abrasions, or after dental extraction, demands the investigation of the patient's coagulation time and bleeding time. Normal limits for these are: coagulation time (Lee and White), 4 to 7 minutes; bleeding time (Ivy), 1 to 4 minutes. If these times are found to be prolonged it is possible that they may be brought within normal limits by the administration of calcium and alkalis or by blood transfusion. If these limits cannot be attained, then the question of operation, the risks of which should be explained to the patient, must be reconsidered. Unless it is absolutely necessary tonsillectomy should be deferred.

4. *Menstruation.*—On account of the psychological upset and the delayed coagulation time of the blood, operation should be avoided just before or during the first few days of a menstrual period.

5. *Jaundice.*—Tonsillectomy is contraindicated in the presence of jaundice due to any cause.

6. *Anaemia.*—In any severe anaemia operation should not be undertaken without preliminary treatment or even a blood transfusion.

7. *The Type of Patient.*—It is interesting to note the physical characteristics of any patient, for it is in those of the plethoric type, with short thick necks, that haemorrhage is most prone to occur. Heavy smokers, chronic alcoholics, and patients with highly excitable and emotionally unstable temperaments also suffer in this same respect. (All sandy-haired children are suspect.) Again, red-haired females and the subjects of thyrotoxicosis show a tendency to bleed excessively following operation.

As a routine, adult patients should be given 10 grains of calcium lactate thrice daily for three days before tonsillectomy, and be asked to abstain from alcohol and tobacco for a similar period.

Operative

Consideration of the various methods of tonsillectomy does not come within the scope of this paper, but the type of operation performed, however, does influence the incidence of severe post-operative haemorrhage. In a large series severe bleeding occurred in 2.6 per cent. of cases after guillotine enucleation, as compared with 0.7 per cent. of cases following removal by dissection (McNally, 1927). The figures will depend to some extent, of course, on the care and discrimination exercised by the individual surgeon in his selection of cases for operation.

It is a significant fact that patients who have been subjected to guillotine enucleation of tonsils nearly always vomit after operation, and the vomitus always contains blood. Douching the face and neck with ice-cold water at the end of the operation induces considerable reflex vasoconstriction and is usually sufficient to cause cessation of the haemorrhage, but it must be remembered that although bleeding may apparently have ceased, in that blood is not trickling from the mouth, a lightly anaesthetized patient may be swallowing the blood. It is important, therefore, that the actual tonsillar fossae should be inspected at the end of the operation and that the patient should not be sent back to bed until all bleeding has been controlled. In cases in which the adenoids have

been removed at the same time care should be taken to ascertain that no tags are left behind, for such tags are a potent source of post-operative haemorrhage.

Removal of tonsils by dissection has for most surgeons now become the operation of choice. Whatever method of dissection is employed the important point is that the *tonsillar fossae must be dry before the patient leaves the operating theatre*. The subsequent maintenance of haemostasis is influenced by the following factors.

1. *Anaesthesia*.—Chloroform anaesthesia, or very deep anaesthesia produced by any agent, results in a fall of blood pressure. Later, when this pressure regains its normal level, haemorrhage may recommence owing to separation of a clot in the mouth of a blood vessel divided, but overlooked, at the time of operation.

2. *Imperfect Clot Formation*.—This is most likely to occur in the larger veins in the bed of the tonsillar fossa. If a vein has been "button-holed," but not completely divided, any obstruction to respiration may cause dilatation of the vein and consequent instability of the clot. Complete division of a large longitudinal vein results in continuous bleeding from its upper end at the time of operation, and for this reason the upper end is usually ligatured. The lower end, however, is collapsed and its contained clot is small. Subsequent dilatation of this lower end renders the clot unstable, and haemorrhage is likely to recur. It is important, therefore, to search for, and tie, the lower end of a completely severed longitudinal vein.

3. *Obstruction to Respiration*.—The maintenance of a clear airway is of the utmost importance following tonsillectomy. Before the patient leaves the operating theatre an artificial airway should be very gently inserted in the mouth after all the blood clot has been removed from the nose and nasopharynx.

4. *Ligatures*.—The slipping of insecurely tied ligatures may be responsible for the occurrence of post-operative haemorrhage.

5. *Artificial Means employed to Control Bleeding at Operation*.—The use of vasoconstricting agents—for example, adrenaline hydrochloride solution—is not to be recommended at the time of operation because subsequent reactionary vasodilatation occurs and may result in capillary oozing. The same objection, however, does not apply to the use of haemostatic sera and snake venom, for these are purely coagulating agents.

Post-operative

Any conditions which tend to cause congestion after operation should be rigorously avoided. The following measures are calculated to minimize the risk of post-operative haemorrhage.

1. On return from the theatre the patient is placed in bed in the "lateral" position. This position allows of free respiration and consequently minimizes congestion. It also permits any blood which may collect to run out of the nose and mouth and so be seen rather than remain concealed. Further, the risk of inhalation of blood or blood clot is considerably reduced.

2. The artificial airway should be removed when the cough reflex has returned.

3. If the patient is becoming restless soon after operation, and provided there is no bleeding, a sedative should be given. For adults, 1/6 grain of omopon is recommended, and for children an enema containing bromides (up to 120 grains) and aspirin (up to 30 grains), combined with a little citric acid, will be found most useful.

4. No hot fluids or food should be allowed during the first twenty-four hours. The diet should be restricted to cold fluids or semi-solid food for the first day, and then gradually increased. Hard or irritating articles of food should be avoided until the tonsillar fossae have healed completely.

5. The patient is allowed out of bed for the first time on the evening of the third day following operation.

6. Hot baths are inadvisable for the first ten days after tonsillectomy.

7. For a week after leaving hospital the patient should avoid any strenuous exercise and should go for short walks only towards the end of the week. During this week he should also refrain from taking any stimulants and should be careful to avoid infection. It is unwise to go to cinemas or theatres during this period.

8. A mixture containing potassium chlorate, sodium salicylate, and sodium bicarbonate is given thrice daily throughout the period of convalescence. The potassium chlorate, after absorption, is secreted in the saliva, and, as is well known, its antiseptic properties are due to the fact that it is a powerful oxidizing agent. It also increases the alkali content of the plasma and is credited with haematinic properties. The sodium salicylate, in addition to its usual antipyretic properties, possesses an almost specific action in cases of infection of a rheumatic nature. Further, it increases the number of leucocytes in the circulating blood.

TYPES OF HAEMORRHAGE

Haemorrhage following tonsillectomy may be divided into three types.

(a) *Reactionary haemorrhage*, or haemorrhage occurring within the first twenty-four hours after operation.

(b) *Haemorrhage during Convalescence*.—This commonly occurs on the fifth night after operation, and is associated with the aseptic separation of the primary slough from the bed of the tonsillar fossa. It is not the result of infection, for it usually occurs in the absence of signs of local inflammatory reaction and in patients whose post-operative temperature is normal. The fact that catgut ligatures also tend to come away at this time again favours the occurrence of haemorrhage on or about the fifth day.

(c) *True Secondary Haemorrhage*.—This differs essentially from the type just described, in that it is associated with damage to the muscular tissue in the bed of the tonsillar fossa and is due to consequent sepsis, which results in sloughing of part of the wall of an artery. Examination of the throat in these cases usually reveals considerable redness and oedema of the faucial pillars and uvula, and sometimes an offensive slough in the tonsillar fossa. The local inflammatory reaction is reflected in the patient's temperature chart. True secondary haemorrhage may occur at any time from the third to the twelfth day after operation.

MANAGEMENT OF A CASE OF HAEMORRHAGE

Reactionary Haemorrhage

Slight oozing, which should be of insignificant amount, usually takes place during the first hour after operation but ceases at the end of this time in the vast majority of cases. If free oozing occurs after the first hour, or if there is vomiting of freshly swallowed blood, the patient must be considered to be suffering from *reactionary haemorrhage*. This is treated according to the following routine procedure:

If a sedative has not been needed, or has not been given already, one should be given now. For this purpose there is no more efficient drug than morphine hydrochloride, which not only lowers the blood pressure but also diminishes the tendency to post-operative vomiting. I am of the opinion that, in the case of adults, an initial dose of one-quarter of a grain administered by hypodermic injection is far more effective than a dose of one-sixth of a grain repeated at the end of half an hour. One-eighth of a grain may be given to a child aged

10 years, but in younger patients morphine or any of its derivatives should be avoided. A mixture containing potassium bromide and chloral hydrate is a safe and efficient sedative for these children under the age of 10.

Unless the haemorrhage is so free as to necessitate urgent attention it is now wise to wait for twenty or thirty minutes before examining the throat. At the end of this time the examination is usually accomplished without difficulty, for the morphine has minimized pain, diminished the throat reflexes, and allayed to some extent the nervous anxiety of the patient.

Whenever morphine or one of its derivatives has been given, the *tonsillar fossae* must be inspected half an hour after the administration of the drug. The surgeon should make this examination himself and not merely rely on the report of possibly indifferent observers. Careful search should be made to detect any oozing or trickling from the fossae, for, although a nurse may say that there has been no further bleeding, the patient may still be swallowing blood. This may accumulate slowly in the stomach to such an extent that the pulse rate may rise alarmingly immediately after a pint of blood has been vomited. It is not uncommon for a patient to go to sleep after morphine has been given and for the doctor to be informed that there is no further bleeding. Two hours later, however, the patient may suddenly waken and vomit a large quantity of blood.

DETAILS OF EXAMINATION AND TREATMENT

A good source of illumination is essential for this examination, and in order to leave both hands free a head-lamp or head-mirror should be employed. If it is thought that haemorrhage is still continuing, the patient is given a tumblerful of cold water and is asked to rinse out the mouth three or four times. The rinsings are voided into a basin. A final mouthful is then taken and swallowed. This renders the mouth fairly free from blood and facilitates inspection of the tonsillar fossae. If on inspection there is no bleeding, further action is unnecessary. If there is bleeding the tongue is depressed gently but firmly by means of a tongue depressor held in one hand and, with an instrument such as Luc's ethmoidal forceps held in the other, all blood clot is removed from the offending fossa. Another mouth-wash of cold water is then given. Total removal of the clot may be all that is necessary to terminate the bleeding. If haemorrhage continues a pledget of cotton-wool, soaked in peroxide of hydrogen and then wrung nearly dry, is inserted into the tonsillar fossa. The tongue depressor is then removed and the patient is allowed to close the mouth on the forceps, the pledget of wool still being pressed into the fossa. At the end of a minute the wool is removed and a fresh but similar pledget applied in the same manner as the first. If necessary, yet a third pledget is applied.

If at the end of three minutes haemorrhage is still occurring, this whole procedure is repeated, substituting a 1 in 1,000 solution of adrenaline hydrochloride for the peroxide of hydrogen. These measures usually suffice to control the bleeding. A warning may be issued at this point. On no account must a solution of *cocaine* and adrenaline be applied to the raw bed of the tonsillar fossa. The use of such a solution may rapidly prove fatal.

Other agents which may be employed in the treatment of reactionary haemorrhage are:

1. *Ice*.—The patient may be given small pieces of ice to suck. This is of questionable value from the haemostatic point of view, but it does allay thirst and also lessens the tendency to

vomit. An ice-pack (or cold-water pack) applied round the neck is sometimes of value in doubtful cases.

2. *Coagulating Serum*.—If available this may be applied locally or administered by injection. In the latter case the danger of anaphylaxis must not be overlooked, and the surgeon must not allow himself to be lulled into a false sense of security merely because haemostatic serum has been given.

3. *Clamps*.—If bleeding is brisk it may be controlled temporarily by the application of a suitably padded clamp of the Courtenay Yorke or Watson-Williams design. Clamps should be applied firmly, but not so tightly as to traumatize the tissue between the blades. If possible their use should be avoided altogether, as they are responsible for much discomfort to the patient.

If the measures taken appear to have stopped the bleeding, the patient is allowed to rest for a while in order that the morphine may be given a chance to complete its work. The pulse rate is recorded at fifteen-minute intervals and a careful watch maintained for further signs of haemorrhage. If haemorrhage does appear to continue, or if in spite of no apparent bleeding the pulse rate is rising, the tonsillar fossae should be inspected again. If the measures enumerated above have not been successful in controlling the bleeding, arrangements should be made for the return of the patient to the operating theatre without delay. I make this statement because I am convinced that it is better to give a second anaesthetic while the patient's general condition is still relatively good than to wait until his state is so precarious that the operative campaign must necessarily be hazardous to a degree. These remarks apply even more forcibly in the case of children and elderly people, who are particularly intolerant of continued haemorrhage and in whom any unnecessary delay in securing haemostasis may prove fatal. A steadily rising pulse rate, a pulse that is irregular or easily compressible, increasing pallor, a cold and clammy skin, shallow and rapid respiration, great restlessness, and the continued vomiting of blood are all danger signs to be avoided rather than treated when they occur.

As soon as the decision to take the patient back to the theatre has been made a hypodermic injection of 1/100 grain of atropine sulphate is given. The anaesthetic of choice on this second occasion is "open" ether, which is well tolerated by these morphinized and exsanguinated patients. On no account should chloroform be administered, for it not only exerts a toxic influence on the myocardium but lowers the blood pressure and consequently conceals haemorrhage. If an injection of coagulating serum has not been given already, it may be administered with advantage while the patient is under the anaesthetic.

A gag is inserted in the mouth and once more all clot is removed from the offending fossa in order to expose the source of the haemorrhage. Single bleeding points are clamped and ligatured. It may be necessary to underrun a bleeding vessel with a catgut suture threaded on a small curved needle. If there is a general ooze a swab soaked in iced acriflavine (1 in 1,000) solution is inserted into the fossa and held there for three minutes. If this fails to control the bleeding a swab soaked in pure turpentine may be tried. The local application of haemostatic serum, or snake venom if available, may also prove effective in controlling a general ooze.

If all the above measures fail, the faucial pillars should be sutured together over a gauze plug or a gauze-covered pledget of wool soaked in the acriflavine solution. Two sutures suffice; they, and the wool, are removed after twenty-four hours. Recourse to suturing the faucial pillars is, however, rarely necessary.

Haemorrhage during Convalescence

In the vast majority of cases haemorrhage of this delayed type occurs on the fifth night following operation and is due to factors already enumerated. As a rule it is not severe, and may consist only in the patient coughing up a small bright red clot. It usually ceases after a gargle of weak hydrogen peroxide. Sometimes the haemorrhage, although not severe, continues during the course of an hour or more, and is associated with discomfort in the throat due to the presence of clot. The patient's efforts to dislodge the clot may then prolong the bleeding, in which case the treatment becomes exactly the same as that already described for reactionary haemorrhage. It will be found, however, that it is rarely necessary to give morphine, still more rare to have to remove the clot, and extremely rare to have to take the patient back to the theatre.

True Secondary Haemorrhage

Haemorrhage of this type is much more serious than that described under the heading of haemorrhage during convalescence. Fortunately, however, it is also more uncommon. When it does occur there is frequently a small "warning" haemorrhage on one day, followed by a larger one within the next twenty-four hours. In such a case it is likely that the patient will have to be taken back to the operating theatre. The control of this type of bleeding is often difficult, for it is seldom possible to clamp and ligate a single bleeding point on account of the friability of the sloughing and oedematous tissues of the bed of the tonsillar fossa. If the more simple measures already advocated for the control of bleeding are ineffective, recourse to suturing the faucial pillars will be necessary.

Ligation of the external carotid artery and the use of snake venom are measures of questionable value in the control of post-operative haemorrhage of this type. According to the literature ligation of the external carotid artery is of doubtful efficacy in any type of tonsillar haemorrhage on account of the extensive anastomosis of this vessel through the circle of Willis. Blood transfusion may be helpful—even life-saving—in cases of severe haemorrhage, but it is desirable that effective measures for the control of any bleeding should be instituted before transfusion becomes necessary.

I wish to express my gratitude to Mr. C. P. Wilson for his helpful advice and criticism during the preparation of this paper.

PERFORATED PEPTIC ULCER IN
ORGANIC NERVOUS DISEASE

BY

ALAN H. HUNT, B.M., F.R.C.S.

Senior Demonstrator of Morbid Anatomy and Histology,
St. Bartholomew's Hospital

AND

ERIC C. O. JEWESBURY, B.M., M.R.C.P.

Chief Assistant to a Medical Unit and to the Neurological
Clinic, St. Bartholomew's Hospital

The following two cases, in which death resulted from diffuse peritonitis due to perforation of a peptic ulcer, occurred within a little while of each other at St. Bartholomew's Hospital. Both patients were suffering from an organic disease of the nervous system, which masked the symptoms and signs of perforation, so that the complete condition was recognized only at necropsy.

Case I

A woman aged 41 was admitted to a medical unit on February 21, 1938, complaining of a pain in the shoulders. Ten years previously a diagnosis of disseminated sclerosis had been made, following some loss of the use of her legs. Similar attacks and remissions had occurred since. Two months previously she again lost the use of her legs, felt unwell, and vomited for a few days. She had experienced vague abdominal discomfort since. Three days before admission she developed sudden severe pain in both shoulders. Her bowels had not been opened subsequently.

On admission she was collapsed, clammy, cyanosed, and dyspnoeic. She complained of pain and tenderness of the shoulders, and she looked moribund. Her temperature was 98° F., pulse 160, and respirations 36. She showed no nystagmus. Her tongue was furred. There were no abnormal physical findings in her chest beyond the tachycardia and tachypnoea. Her abdomen was distended and tense, but rigid, and there was slight tenderness on deep palpation. The percussion note was resonant all over, and the area of liver dullness was reduced. There was spasticity of the left lower limb with increased knee-jerk and extensor plantar response. The temperature and pulse showed no marked variation, and she died the following day.

Post-mortem Examination.—The typical grey translucent scars of disseminated sclerosis were found throughout the cerebral hemispheres and, to a lesser extent, the cerebellum and spinal cord. The largest was 1 cm. in diameter and occupied the greater part of the right side of the pons. The heart was moderately dilated. Both pleural cavities contained small serous effusions, and the lungs showed emphysema and terminal congestion. The greater sac of the peritoneal cavity was distended with much gas and two pints of foul turbid fluid. The lesser sac contained an abscess cavity surrounded by dense fibrous tissue, but anteriorly the abscess had perforated through the gastro-hepatic omentum into the greater sac. This perforation was 1 cm. in diameter, and was situated midway between the cardia and pylorus. In the stomach a chronic peptic ulcer was discovered on the posterior wall immediately proximal to the pylorus. Its floor was completely deficient, and this hole communicated directly with the abscess cavity in the lesser sac. Just proximal to this perforation there was also a subacute ulcer 2 cm. in diameter.

Case II

A man aged 55 was admitted to a medical unit on March 18, 1938, complaining of feeling weak. One hour previously, while walking in the street, he had suddenly "come over queer" and felt some pain in the back of the shoulders. He passed a loose motion, his vision became dim, and he collapsed, though he was never unconscious.

The Fifth Biennial Conference on Mental Health will be held at the Central Hall, Westminster, London, S.W.1, from January 12 to 14, 1939. The conference luncheon will take place at the Hotel Victoria, W.C.2, on January 13. The subjects for discussion at the sessions of the conference are as follows: January 12, Is our national intelligence declining? Should mental treatment be practised solely by doctors? January 13: The psychological factor in sexual delinquency; The organization and staffing of out-patient mental treatment clinics; Mental hygiene and the Press. January 14: Education and emotional needs of the child; Problems of adolescent instability and of juvenile delinquency; The place of the social worker in mental health. Tickets and information can be obtained from the Secretary, The National Council for Mental Hygiene, 76/77, Chandos House, Palmer Street, London, S.W.1.

On admission he was cyanosed and sweating, but not in pain. He appeared very shocked, but answered questions normally. His temperature was 95° F., pulse 88, and respirations 22. His pupils reacted to accommodation but not to light. His tongue was furred. The cardiac impulse was feeble and the heart sounds were faint but regular. The blood pressure was 58/30 mm. Hg. Some rhonchi and medium rales were heard at the lung bases, but his chest appeared otherwise normal except for a band of anaesthesia over the upper part. His abdomen was soft and not distended, with some tenderness in the right hypochondrium. The right flank was dull on percussion and the area of liver dullness was diminished. The knee-jerks were absent and the plantar responses were flexor. There was a patchy anaesthesia on the outer sides of the legs. The following day he was still cyanosed and weak, but free from pain. The most striking change was the increasing distension of his abdomen. The percussion note had become drum-like, and the liver dullness was now obliterated. No flatus was passed on the insertion of a rectal tube. His temperature in the morning was 98.4° F., the pulse 80, and the respirations 17. The absence of pain or much tenderness, and the steadiness of the temperature and pulse rate, were outstanding features. He became progressively weaker, and died the same day.

Post-mortem Examination.—The air passages contained regurgitated stomach contents. There was a small serous effusion in each pleural cavity and the lungs showed terminal congestion and oedema. All chambers of the heart were dilated and the muscle was soft and friable; the valves were normal. There was atheroma but no other abnormality of the aorta and coronary arteries. The peritoneal cavity was greatly distended with gas and foul turbid fluid. In the stomach, just proximal to but also involving the pylorus, was a perforated chronic peptic ulcer with a crater measuring 2 cm. in diameter. The whole of the floor of the ulcer was deficient.

Discussion

In neither of these cases is the history or physical examination at first suggestive of perforated peptic ulcer. The existence of a disease of the nervous system was known (disseminated sclerosis and tabes dorsalis respectively), but the reason for the collapse was discovered only at necropsy. In the first case medullary failure from a plaque of sclerosis was considered a possible cause; in the second, tabetic crisis, coronary thrombosis, and perforated peptic ulcer were suggested, but no conclusion was arrived at. Both patients were collapsed, but neither of them gave a history of severe abdominal pain. The only pain of any consequence that they had experienced had been in the shoulders. The temperature and pulse rates showed no variation, and, although in the first case the pulse was 160, in the second it was only 88 on admission and fell to 80 subsequently. In neither instance was there any abdominal rigidity, nor was there any tenderness except on deep palpation. The most important positive finding, which was common to both cases, was the development of abdominal distension with a very resonant note on percussion and diminution of the area of liver dullness. This became particularly noticeable in Case II.

A review of all the cases of perforated peptic ulcer that have come to necropsy at St. Bartholomew's Hospital during the past decade revealed that during this period there have been two others with organic disease of the nervous system comparable to the two cases here described. The one, a diabetic woman of 62, was suffering from severe peripheral neuritis. She suddenly developed pain in the left side of the abdomen, with rigidity and tenderness only on the right side. She passed no urine, became incontinent of faeces, and died the next morning. At necropsy a large chronic gastric ulcer was found to have perforated, resulting in diffuse peritonitis. Degeneration

of the posterior root ganglia and posterior columns of the spinal cord, more on the left side than on the right, was demonstrated. The other case was that of a tabetic woman aged 49 who had been admitted to hospital for investigation and treatment of intermittent headaches. One night her pulse suddenly became rapid and weak. Her abdomen was found to be tender and rigid and tympanitic on percussion, but she did not complain of anything. She died the next morning, and at necropsy peritonitis due to a perforated peptic ulcer was discovered.

It is recognized that a peptic ulcer may rarely perforate in an otherwise normal patient without producing the typical syndrome, but it is difficult to assess the proportion in which this occurs. Most of the cases reviewed, in which a perforated peptic ulcer had been found only at necropsy, were admitted in a moribund condition and no clear history had been obtained.

The four cases here described are the only instances during the past ten years in which perforation and organic nervous disease were both present, and in all four the history, symptoms, and signs were atypical. In certain organic diseases of the nervous system it is thus evident that a peptic ulcer may perforate without producing abdominal pain or rigidity and without causing an increasing pulse rate. Presumably this is the result of interference with the normal pathway of pain impulses. In such instances, however, progressive distension of the abdomen with a tympanitic percussion note and diminution of the area of liver dullness are in themselves signs of the utmost significance in arriving at the diagnosis.

We are indebted to Dr. Geoffrey Evans and Dr. James Maxwell for permission to report the cases under their care.

ADMINISTRATION OF PITUITARY EXTRACT IN THE THIRD STAGE OF LABOUR

BY

GEORGE W. BLOMFIELD, M.B., Ch.B.

Tutor in Obstetrics and Gynaecology, University of Leeds

It is commonly taught that administration of any oxytocic drug during the third stage of labour is dangerous and inadvisable, in that hour-glass contraction with retention of the placenta and all its attendant risks is apt to result. Here are some conflicting views taken from standard textbooks.

Gibbon Fitzgibbon (1937) says: "There is no place for the drug while the placenta is in the uterus. Its use always entails the risk of imprisoning the placenta by closure of the cervix." Tweedy (1937) also advises against this treatment. Eden and Holland (1937) say that except for experts its use should be limited to the third stage of labour after the placenta has left the uterus. Gibbard (1938) points out the danger of giving any oxytocic drug before the placenta is delivered, on account of the risk of hour-glass contraction. Most American writers, however, are in favour of giving pituitary extract during the third stage. E. A. Schumann (1937) takes the third stage of labour as an indication for administering pituitary extract. He says that 0.5 c.cm. may be given with safety, and adds, "Incarceration of the placenta by a cervix contracted by pituitrin has been reported, but must be quite rare." DeLee (1933) holds that when pituitary extract is administered, which is very often done nowadays after the delivery of the child, the third stage is much altered, and

he goes on to say that the third stage is shortened to five or eight minutes.

At Professor A. M. Claye's suggestion it was decided to test a series of cases in which 1 c.cm. (that is, 10 units) of pituitary extract (or 1 c.cm. of pitocin in toxæmic cases) was to be administered intramuscularly early in the third stage of labour, and to compare them with a similar series of cases in which no oxytocic drug would be given during that stage. This has been carried out at the Leeds Maternity Hospital over the whole year 1937 and part of 1938, until more than 1,000 consecutive cases were obtained for each series.

The experiment aimed at ascertaining: (1) the amount of blood loss post partum; (2) the length of time of the third stage; and (3) any untoward results or dangers which might result. The procedure in all cases was the same. To estimate the blood loss all the blood and clots expelled during or after the third stage were collected until haemorrhage ceased, and the quantity was measured as accurately as possible. No attempt was made to express the placenta until twenty minutes after delivery. It was then expressed if lying in the vagina, but if still in the uterus the procedure was to control the fundus as necessary but not to attempt expression until the placenta had been expelled naturally from the uterus. The surgeon responsible was of course informed, and took the usual steps in cases of post-partum haemorrhage.

Tables A and B give the proportion of cases which fall into different categories as regards quantity of blood loss—A in the control series and B in the pituitrin series. Table C gives the proportion of cases in which the placenta was retained more than one hour. For the purpose of correct comparison the natural deliveries (of which there are 1,368 in the control series and 1,056 in the pituitrin series) have been separated from the cases of forceps, breech, and twins. It is obvious that the same degree of accuracy could not be obtained in cases where operative obstetric intervention was employed, nor are the results likely to be comparable with cases having a natural delivery. The twins series is not claimed as sufficient in number to be of statistical significance, but of the normal deliveries there can be no doubt that over 1,000 cases in each series are enough to be of statistical value.

TABLE A.—Blood Loss (Post Partum) without Pituitrin during Third Stage

| Type of Case | Total | Blood Loss in c.cm. | | | | |
|----------------------|-------|---------------------|----------------|---------------|--------------|--------------|
| | | 0 to 100 | 100 to 500 | 500 to 750 | 750 to 1,000 | 1,000 + |
| Natural delivery .. | 1,368 | 398 (29.2%) | 799 (58.3%) | 110 (8.0%) | 42 (3.1%) | 19 (1.4%) |
| Forceps or breech .. | 156 | 54 (34.6%) | 86 (55.1%) | 9 (5.8%) | 2 (1.3%) | 5 (3.2%) |
| Twins | 22 | 6 (27%) | 15 (68%) | 1 (5%) | — | — |

TABLE B.—Blood Loss (Post Partum) with Pituitrin or Pitocin 1 c.cm. in Third Stage

| Type of Case | Total | Blood Loss in c.cm. | | | | |
|----------------------|-------|---------------------|----------------|--------------|--------------|--------------|
| | | 0 to 100 | 100 to 500 | 500 to 750 | 750 to 1,000 | 1,000 + |
| Natural delivery .. | 1,056 | 364 (34.5%) | 601 (56.9%) | 54 (5.1%) | 25 (2.4%) | 12 (1.1%) |
| Forceps or breech .. | 118 | 38 (32.2%) | 74 (62.7%) | 4 (3.4%) | 2 (1.7%) | — |
| Twins | 13 | 3 (23%) | 8 (61%) | 1 (8%) | 1 (8%) | — |

TABLE C.—Retained Placenta

| | Type of Case | Total Cases | Hours Retained | No. | Per cent. | Ave. Loss c.cm. | No. of Manual Removals |
|--|--|-------------|-----------------|---------|--------------|-----------------|------------------------|
| Without pituitrin during third stage | { Natural delivery Forceps, breech, twins.. } | 1,368 | { 1-2 2-24 } | 17 3 | 1.25 0.22 | 825 | 2 |
| | | 178 | { 1-2 2-24 } | 5 3 | 2.8 1.7 | — | 1 0 |
| | | | { 1-2 2-24 } | 3 3 | — 2.3 | — | 0 1 |
| With pituitrin or pitocin during third stage | { Natural delivery Forceps, breech, twins.. } | 1,056 | { 1-2 2-24 } | 10 3 | 0.95 0.26 | 753 | 0 |
| | | 131 | { 1-2 2-24 } | 9 3 | 6.9 2.3 | — | 1 1 |
| | | | { 1-2 2-24 } | 3 3 | — 2.3 | — | 0 1 |

It will be seen from Tables A and B that whereas 12.5 per cent. (8 + 3.1 + 1.4) of the natural deliveries in the control series are associated with a post-partum loss of more than 500 c.cm., only 8.6 per cent. (5.1 + 2.4 + 1.1) suffer this loss among the natural deliveries in the pituitrin series. In fact, it is noticeable that the general shift in the pituitrin series is towards the left—that is, towards a smaller haemorrhage.

Table C shows that there are twenty-eight cases of retained placenta in the 1,546 patients of the control series, as compared with twenty-five cases of retained placenta in the 1,187 patients of the pituitrin series. Out of these there were three cases of manual removal with one death in the control series and two cases of manual removal with no death among the pituitrin series. The haemorrhage was slightly less in the pituitrin series, the average loss being 753 c.cm., compared with 825 c.cm. in the control series; in cases of natural delivery where the placenta was retained from 60 to 120 minutes. The biggest recorded haemorrhage was among the control series, being over 3,000 c.cm. The patient was given several blood transfusions and made a good recovery.

With regard to contraction ring, only two cases were definite in each series. These, as might be expected, occurred in cases of retained placenta.

Conclusions

The results of this experiment are claimed to show: (a) that there is no danger whatever in giving 1 c.cm. of pituitrin or pitocin during the third stage of labour; (b) that the amount of haemorrhage is not much affected: in the series there was a tendency to a smaller post-partum loss in the pituitrin cases.

It is not claimed that posterior pituitary extract should be given in the third stage as a routine treatment for all cases, nor should control of the fundus or the very watchful care that is necessary at this stage be relaxed, or be replaced by an oxytocic drug.

I am indebted to Professor A. M. Claye and Mr. David Currie for the clinical material, and also to Dr. R. H. B. Adamson and Mr. B. L. Jeaffreson, under whose care many of the control patients were admitted.

Clinical Memoranda

Fracture-dislocation at the Ankle

The method used in the treatment of this case is, I think, worth reporting. The anatomical and functional recovery has been excellent, in spite of a severe injury.

CASE RECORD

On December 19, 1937, a married woman, aged 38, by a trivial accident (tripping over the fender) caused rotation of the ankle-joint through 90 degrees. X-ray examination showed fracture of the fibular malleolus with separation outwards, of the posterior tibial mortise with displacement backwards, and of the astragalus (see figure). The patient was admitted

to hospital, and the same evening, under full anaesthesia, the fragments were brought together. A strip of sponge rubber was cut to shape, with a recess for the calcaneal tuberosity, and bent round the heel from the posterior surface of the ankle to the plantar aspect of the toes. With the knee bent to allow increase of dorsiflexion plaster-of-Paris was applied, special attention being paid to exaggerated plantar adduction. A sole-piece of three-ply wood was laid external to the sponge rubber on the under surface of the foot and incorporated in the plaster. On the third day the patient was allowed to go home; she was not confined to bed, but was able to be lifted to a chair and to be wheeled out.

The plaster was left untouched for nine weeks. On February 21, 1938, it was replaced by an aluminium splint and foot-piece. In this she was encouraged to walk, and she wore it for three weeks. Weekly radiant heat and massage were given to the leg and ankle until April 2, fifteen weeks after the injury, when further treatment was considered unnecessary.

Since then she has carried on her ordinary work without disability. There is no deformity or eversion of the foot, and the functional recovery can be regarded as 95 per cent. of normal. The method employed seems justified by the result.

Bourne, Lincs.

Autochthonous Urethral Calculus

I should like to place on record the following case of giant urethral calculus.

A man aged 52 was admitted to hospital complaining of pain and a swelling in the perineum, and gave the following urinary history.

In 1907 he made an uneventful recovery from gonorrhoea and remained well until 1930, when he had the misfortune to be kicked between the legs while stooping to shoe a mule. During the fourteen days immediately following the kick he had haematuria on five different occasions, followed by a perineal abscess, for which he was admitted to hospital, where a catheter was passed into the bladder left *in situ*, and the abscess incised. The abscess drained well and finally healed in three weeks, and he would have been discharged from hospital but for an unfortunate mishap. In an effort to unblock the indwelling catheter by the injection of a syringe of water the tip of the catheter was blown off into the bladder. Three days later the perineal wound broke down and started to discharge blood-stained urine. Suprapubic cystotomy was performed forthwith, and the catheter tip removed from the bladder. The suprapubic wound healed in three weeks, but it was not till ten months later that the perineal sinus closed.

Two portions of the calculus removed from the urethra, sectioned to show the interior.

Micturition remained normal until January, 1938, when he became incontinent, much dribbling following the act. Then a sharp pain brought to his notice a lump in the site of his old sinus. With increasing difficulty in voiding urine the patient experimented, and discovered that by manipulating the lump in the perineum the passage of urine could be facilitated. There was no mention of renal colic at any time. Micturition became increasingly painful, and he attended Westminster Hospital for the first time on March 24, 1938.

On examination the patient was found to have acute retention, the bladder being half-way up to the umbilicus. In the perineum, in the line of the urethra, could be felt a hard smooth mass about the size of a hen's egg. Examined per rectum, the mass was found to be located in front of the triangular ligament, and the grating of two hard surfaces could be distinctly noted; this confirmed the diagnosis of urethral calculus.

He was operated upon immediately. A metal sound was passed down to the stone and an incision made over it in the perineal line of the urethra. I then removed four portions of a stone, lying behind the stricture, from a widely dilated urethra. While guiding a catheter into the bladder a small papilloma was noticed on the wall of the urethra; this was removed, sectioned, and reported upon thus: "There is metaplasia of epithelium; the whole surface of the growth is covered with a well-differentiated squamous layer. No evidence of carcinoma." The perineal incision closed in fourteen days and micturition is now normal.

Chemical examination of the stone, which weighed 24 grammes, showed it to consist of calcium phosphate.

I am indebted to Mr. Rock Carling for the opportunity of publishing this case.

J. GRAHAM, M.R.C.S., L.R.C.P.

Reviews

THE BART'S REPORTS

St. Bartholomew's Hospital Reports. Volume LXXI. (Pp. 353; illustrated. 21s. net.) London: John Murray. 1938.

A general impression of the fifteen main original papers in the seventy-first volume of the *St. Bartholomew's Hospital Reports* is the value of the follow-up system of the hospital patients, the medico-surgical authorship of articles, and the underlying influence of neurosurgery shown in some of the contributions. Drs. George Grahame and W. G. Oakley analyse, with the help of the follow-up department, the complications and fate of a hundred patients, fifty-three males and forty-seven females, suffering from diabetes mellitus. Neurological complications, in twenty-nine cases, occurred with increasing frequency among the older groups of patients, the most tiresome symptom being pains in the legs. Arterial changes occurred in fifteen patients, and the authors explain why they consider it wrong to insist on keeping dry an ulcer on a diabetic's foot. The report of the cancer department, of which Mr. Malcolm Donaldson is the director, covers a wide field, and shows wide activity in the following up of patients. Sir Girling Ball, the treasurer of the *Reports*, writes on the end-results of traumatic rupture of the urethra in children. In the article on the treatment of angina of effort and of spasmodic angina by thyroidectomy Dr. Geoffrey Bourne shows that twelve cases, carefully chosen out of three hundred attending the cardiac pain follow-up clinic at St. Bartholomew's, did extremely well, and Professor Paterson Ross, in notes on the surgical aspects of total thyroidectomy, mentions that the operation diminished the susceptibility to adrenaline injections. Dr. Avery Jones and Mr. Naunton Morgan of the two professorial units discuss the post-operative administration of fluids. Sympathectomy for erythrocyanosis frigida and chronic oedema of the legs is considered by Mr. G. C. Knight of the surgical professorial unit, and Mr. Boyd, also of the same unit, contributes two excellent articles on thrombo-angiitis obliterans and on the effect of total and subtotal resection of the stomach on blood formation in dogs, as bearing on the occurrence of macrocytic anaemia after gastrectomy in man. In an extremely interesting analysis of a hundred cases of prostatic carcinoma Mr. McGavin concludes that it has not any aetiological relation to benign hypertrophy. There is a sympathetic *In Memoriam* of the late Mr. R. C. Bailey, and a full and in every way admirable life of Samuel Gee is given by the winner of the Wix prize for 1937, Mr. Oliver Garrod.

PATHOLOGICAL TECHNIQUE

Pathological Technique. A Practical Manual for Workers in Pathological Histology, including Directions for the Performance of Autopsies and for Microphotography. By Frank Burr Mallory, A.M., M.D., S.D. (Pp. 434; 14 figures, 6 tables. 20s. net.) Philadelphia and London: W. B. Saunders. 1938.

F. B. Mallory is one of the greatest living masters of histological technique, and the originator of several valuable staining methods; he has now published a book entitled *Pathological Technique*, which it is safe to say will at once attain the status of a classic. Naturally the greater part of it is devoted to descriptions of staining methods, and it is chiefly for these that the book will be found so valuable a work of reference. The directions

given are such as can only come from long experience; they omit no detail, forestall hidden difficulties, and for a subject so full of technicalities are unusually readable. There are also chapters on post-mortem technique, museum methods, and photomicrography, and a bibliography and a good index. There is little discussion of the chemistry and mechanism of staining methods, and from the practical point of view this would be superfluous. In connexion with many methods it would also be unprofitable, since they are purely empirical, but the histologist often asks himself why a reagent will do what it does, and indeed why it was ever tried for the purpose, and when there is any answer to these questions it would perhaps be helpful to know it.

VOLUNTARY SOCIAL SERVICE

The Voluntary Citizen. An Enquiry into the Place of Philanthropy in the Community. By Constance Braithwaite, B.Sc., Ph.D. (Pp. 341. 7s. 6d. net.) London: Methuen and Co. 1938.

This book with its rather curious and awkward title is by a lecturer in the social study department of the University of Birmingham, and it deserves the consideration of those interested in local government or in the social services—especially, perhaps, of medical practitioners who are so interested. The title, no doubt, serves sufficiently to indicate that the book is concerned with the status and functions of the voluntary social worker or administrator, but surely everyone is a citizen willy-nilly. The book is in three sections, quite different in character though not unrelated to each other, and the emphasis of attention among these given by different readers will undoubtedly vary. Part I is devoted to the evolution of what the author calls a "philosophy of philanthropy," and discusses the case for public social services, the limitations of such State provision and the need for certain varieties of voluntary organization and effort, the place of voluntary personal service whether as social worker or administrator and whether under public or independent auspices, and the relation of philanthropy to a socialist system. Part II is concerned with the income of charities in England and Wales and its relation to the contribution of public finance, as ascertained mainly by an examination of the charities in London and in Liverpool and of statistics relating to voluntary hospitals. Part III describes in some detail the work and finance of district nursing associations, considering them as typical charities and an example of a voluntarily organized social service, and studying them as they function in a large city (Birmingham), a small town (Banbury), and a rural area (part of Oxfordshire). Each of these sections contains valuable material excellently presented.

The conclusions of the second section will possibly surprise many by revealing the relatively small proportion borne by charitable gifts to the various social services as compared with that borne by State or community funds. Of the social services in general, philanthropy bears under 10 per cent. of the cost, and as regards hospital services not more than 25 per cent. Under these circumstances, as well as on other grounds, the argument of the first part of the book is of much importance. It is presented frankly from the socialist point of view, but it is perhaps the more valuable on this account. Many readers will not be sympathetic towards the ultimate organization of society desired by the writer, and some may like to consider along with this book the views of Mr. J. Q. Henriques, whose volume *A Citizen's Guide to Social Service* was the subject of a leading article in the *Journal* of September 24 last (p. 666). Dr. Braithwaite is, how-

ever, always clear and fair in her statements, and logical in her arguments if her point of view be accepted; and she envisages a much wider scope and more important place for voluntary activity and personal service, both in the present and in the future, than are usually conceded by socialist thinkers and writers. A welcome feature of her discussion is her powerful plea for the much wider exercise by local government councils of their power of co-opting on to their committees and subcommittees persons of experience who are not members of those councils themselves. It is to be hoped that these pages will come to the notice of such members and that they will have their much-needed practical effect.

CHEMISTRY OF THE BRAIN

Chemistry of the Brain. By Irvine H. Page, A.B., M.D. (Pp. 444; 52 tables, 34s.) London: Baillière, Tindall and Cox, 1937.

Dr. Irvine Page's book is entitled to a notable place among recently published scientific works. There has existed a real need for a volume which would collect and co-ordinate the widely scattered results of research work on the chemistry of the brain, and no better authority could have been found to undertake this rather difficult task than Dr. Page, himself the author of many important publications in this field.

Beginning with a tribute to the father of brain chemistry, Thudichum, he proceeds immediately to the foundation subject of his book—the chemistry of the lipids—and emphasizes the importance of the part played by these substances of which the brain is largely composed. Incidentally, it may be pointed out that here we have the lipids treated in a clear and comprehensive manner unsurpassed in any biochemical literature. Thereafter with undiminished thoroughness the several sections deal in turn with the other classes of biochemically important substances—carbohydrates, proteins, electrolytes, vitamins, and enzymes—in their relation to brain tissue metabolism. Important chapters concern also physicochemical aspects and comparative neurochemistry, while the final section on oxidation and reduction has been entrusted to no less an authority than Dr. Quastel. Wherever possible the more academic advances have been brought into their true relation with investigations on the clinical side, with the result that the book is as instructive to the clinician as it is to the biochemist.

Despite all that has so far been accomplished some disappointment might be felt that chemical investigation has produced relatively little in the way of practical contributions to the development of psychiatry; but readers will not fail to realize that the ground is being well prepared, and, with the filling in of certain important gaps in our knowledge, there will soon come a time when the high expectations of the pioneers in this branch will be amply fulfilled.

ESSENTIALS OF SURGICAL PRACTICE

Everyday Surgery. By Lambert Rogers, M.Sc., F.R.C.S., F.R.C.S.Ed., F.R.A.C.S., F.A.C.S., and A. L. d'Abreu, M.B., Ch.M., F.R.C.S. With an Introduction by Professor G. Grey Turner, D.Ch., M.S., F.R.C.S., F.R.A.C.S., F.A.C.S. (Pp. 280; 160 figures. 12s. 6d. net.) London: Edward Arnold and Co., 1938.

In *Everyday Surgery* the authors, Professor Lambert Rogers and Mr. A. L. d'Abreu, present in a concise form what they regard as the best in modern surgical practice of an everyday as opposed to an unusual or special character. In the introduction, which is packed with clinical wisdom, Professor Grey Turner lays stress on the

important axiom that everyday surgery involves the broad principles which apply to surgery in general and that these principles cannot be dissociated in the mind of those responsible for treatment, however insistent and important the details of treatment may be.

The intention of this book is to focus the mind on essentials. In this the authors have been very successful. The whole field of surgery as met with in ordinary practice is covered, but the special departments are not dealt with. Of necessity the opinions expressed are dogmatic and represent the views of the authors and not necessarily the ideas of other surgeons, though it would be difficult to pick out any controversial statements throughout the book. The scheme followed in each chapter is to outline the broad features of the subject and the appropriate method of treatment. So much ground is covered in a small compass but with such a definitely practical trend that this book should be found very valuable both to students and to those practitioners who, having possibly lost touch with modern surgical practice, wish to obtain the most up-to-date guidance. We could find no reference to Crohn's disease. To mention this omission may savour of straining at a gnat, and the authors are probably right in regarding this disease as falling outside the definition of an everyday condition. Even so, the practitioner seeking guidance in such an up-to-date book as this might pardonably be disappointed at finding no reference to it.

The illustrations are in the form of line drawings, and they are exceptionally clear and to the point. Details of operations have been purposely omitted, though stress is laid upon minor technical procedures. The authors have succeeded in producing a very clear and concise exposition of the outlines of modern surgical practice.

PARASITOLOGY

Die tierischen Parasiten des Menschen By Dr. Walter Stempel. (Pp. 226; 220 figures. R.M. 12. bound, R.M. 13.50.) Jena: Gustav Fischer, 1938.

Parasitology. With Special Reference to Man and Domesticated Animals. By Robert Hegner, Ph.D., Francis M. Root, Ph.D., Donald L. Augustine, Sc.D., and Clay G. Huff, Sc.D. A general revision of *Animal Parasitology* 1929. (Pp. 812; 308 figures, 5 tables. 25s. net.) London and New York: D. Appleton-Century Company, 1938.

Although morbid conditions produced by animal parasites are overwhelmingly encountered in tropical climates, the author of *Die tierischen Parasiten des Menschen* points out in a preface that while the brisk international intercourse of our time makes it impossible even in temperate zones to neglect the importance of these diseases, there does not exist in German any modern, comprehensive, and at the same time concise presentation of the subject. His book, written with sound conservatism, is an admirable attempt to meet the needs of the situation. Opening with a general discussion on parasitism, it follows orthodox lines, describing first the protozoa, then the helminths, and finally the arthropod parasites. While an effort has been made to cover the whole field, the less important parasites are dealt with briefly in small type, so that without destroying the essential compactness of the book it has been possible to give due emphasis to the important sections. At the end there is a chronological index of the more important literature bearing on the subject, which will enable those interested to pursue their studies further, although there are omissions which may surprise the English reader. Supplemented by practical work the book will provide a useful and handy textbook for the German student or practitioner. The volume is generously illustrated with good diagrams and photographs; the paper

and printing are of the excellent quality for which the publishing house is renowned; but the paper binding is too flimsy to be serviceable.

Parasitology, by Dr. Hegner and his fellow workers, sets out to cover the field of parasitology, with especial emphasis on the parasites of man; it is divided into an introduction and three sections. The introduction is concerned with the broad general principles of the subject, such as interactions of parasite and host, and the rules of zoological classification and nomenclature. The first section is devoted to protozoology, the second to helminthology, and the third to arthropods of parasitological importance. In a previous edition the sections were written independently by their respective specialists, and this arrangement has naturally been preserved, except that, owing to the death of the author of the section on medical helminthology, this part has been revised by one of his former students. The arrangement makes for thoroughness, since the field of parasitology is so large and progress in the subject has been so rapid that no single author could adequately encompass the whole. How wide and ambitious is the scope of the book becomes therefore obvious, and indeed it is more diffuse than may be desirable for the average student. It contains, for example, sections on treatment which are outside the scope of what is proper to a book of this nature; the authors appear to feel this, as these sections are so inadequately treated as to be of little practical value. On the other hand, the detail of many sections is hardly sufficient for the advanced worker in parasitology, and although it is stated that every chapter has been carefully revised so as to include the results of additions to knowledge that have been made during the past nine years, there are notable omissions. Nevertheless, a single handy volume dealing with the three branches of parasitology may not be without value to the student or practitioner.

Notes on Books

The dependence of surgeon and patient on the engineer is most strikingly shown in the provision of artificial limbs for those who have suffered amputation. For this reason we welcome the appearance of a small book entitled *Back to Activity*, in which Desoutter Brothers Ltd., of Baker Street, London, describe all that a surgeon and patient should know about artificial lower limbs. It may be advertisement, but it is the kind we like—honest and informative. It shows the marvels that have been achieved in this small but most important development of modern engineering, and, what is even more valuable, the conditions that make for success. Where the surgeon is able to select the site for amputation, he should plan the operation so that the best possible type of limb can be fitted without difficulty; the stump should receive appropriate after-treatment to secure proper shrinkage and good muscular control; and, finally, after the limb has been supplied, the patient must be taught how to use it. This is a good book to leave within reach of a patient who is still stunned by having lost a limb; it will give him just the encouragement he so sorely needs.

In a recent work on popular misunderstandings with regard to medicine, *Doctors don't believe it*, Dr. AUGUST A. THOMEN of New York University cites from a Missouri newspaper the case of a lady who sneezed so violently that one of her eyes fell out. She was promptly conveyed to hospital, and after treatment was discharged with her eye duly replaced and little the worse. The hospital authorities are credited with the statement: "It is not unusual for the eye to be removed for some operations, but to have it forced out by

coughing or sneezing is unique in medical annals." The author confutes these misbeliefs together with 184 others, such as that singeing the hair is beneficial, that tobacco smoke is a disinfectant, that diphtheria is caused by sewer gas, and that ground glass is a deadly poison. He quotes entertaining instances from a variety of sources, and in more serious mood presents lucid summaries of correct medical opinion on diet, genetics, and other subjects. The book, originally published in America, now appears in an English edition with an introduction by Lord Horder (J. M. Dent and Sons, 6s.). Combining as it does fact with fancy, it will be read with profit and pleasure by many, for, as was said of old, *Omne tulit punctum qui miscuit utile dulci*.

Regulationsprüfung des Kreislaufs (Measurement of the Control of Circulation), by Professor FRITZ SCHELLONG, gives an account of important methods elaborated by the author, who is well known for his researches on conduction in cardiac tissue and its excitability. Three tests are used. The first two depend on measurements of blood pressure and pulse rate in the recumbent and upright position and the effects thereon produced by measured exercise. The third test is less familiar, for it consists in measuring the effect of exercise on the duration of the Q.R.S. period. The importance of this last test is that it measures the effect of exercise on the heart itself as contrasted with responses which involve the whole circulatory system. The test depends on the fact that conduction in damaged heart muscle is slower than in normal muscle. Exercise in normal persons increases cardiac frequency and therefore decreases the Q.R.S. duration. In cardiac disease this effect is opposed by the delay in conduction, and hence the Q.R.S. duration is not shortened and may be prolonged. The monograph describes the details of the methods employed and gives an estimate of their diagnostic value based on experience with 2,000 cases. It is published by Theodor Steinkopff of Dresden and Leipzig at RM. 11.

Miss CHRISTINE E. PETERSEN produces from the Columbia University a pleasant little volume on *The Doctor in French Drama, 1700-1775* (Oxford University Press, 11s. 6d.). Being witty herself she has been able to see the fun poked at the French doctors, much of which was well deserved. The result has been a readable essay, made the more valuable by a chronology of the plays and a hand-list of books consulted. There is, too, a good index.

Preparations and Appliances

SIMPLE INHALER

Dr. G. P. HUMPHRY (Abergavenny) writes:

I have improvised an inhaler which allows the patient using it to lie down if he wants to. It consists of eighteen inches of 4/10-bore and three inches of 2/10-bore rubber tubing joined

by strapping. End A fits, or with a bandage can be made to fit, any suitable bottle. End B is held in the mouth. I find that this simple device works perfectly, and the cost is negligible.

Corrigendum.—In our notice of "catdeferrum" tablets (October 29, p. 894) the name of this preparation was misspelt. It should have been made clear that the composition of the tablets stated therein was based upon daily dosage (four tablets), not on one tablet. The manufacturers are Glaxo Laboratories, Ltd.

Nova et Vetera

THE DEATH OF CHARLES II

Those students of medical history who are interested in biography and do not confine their attention to the sterner discipline of research into the development of ideas have long been attracted by the subject of the diseases and deaths of persons eminent in history. On this there is a very considerable amount of material available from both lay and medical sources. Sir Henry Hallford, who holds the record as President of the Royal College of Physicians of London for twenty-four years (1820-44), thereby beating the twenty-three years' presidency (1786-1809) of the Medical Society of London by James Sims, wrote a concise account of *The Deaths of Some Eminent Persons of Modern Times* (1835), including seven kings and Oliver Cromwell. Hallford was a great court physician, and in the *Lancet* his manners were satirized as those of "the eel-backed baronet." More recently Chaplin (1919) illustrated the state of contemporary medicine by the records of the sick-beds of George III and Samuel Johnson, and *The Deaths of the Kings of England* (1913) have been described by J. Rae, and by Macleod Yearsley in *Le Roy est mort* (1935). Of the Kings of England the death of none has received more attention than that of Charles II; in addition to the necrologies just mentioned, there is the notable work *The Last Days of Charles II* (1909), by the late Raymond Crawford, which was appreciatively reviewed in these columns (1909, 2, 1536), and was largely drawn on in the anonymous series of "Some Royal Death-beds" (1910, 1, 1557). Descriptions in language more picturesque than medically accurate were given by Macaulay and J. H. Jesse.

Unfounded Suspicion of Poisoning

The death-bed of Charles II, February 2-6, 1684-5, was remarkable for his kindly references to his Queen and to Nell Gwyn, his apology for taking such an unconscionable time a-dying, for the large number—at least sixteen—of his medical attendants and their unpleasant remedies, which he suffered with unflinching fortitude. The necropsy, recorded by Sir Charles Scarborough, did not show any evidence of poisoning, but was thought to prove that death was due to "apoplexy." Crawford, who suggested that Scarborough's lengthy Latin account was probably written, perhaps at the request of James II, to refute the suspicion of poisoning, convincingly established the diagnosis of chronic interstitial nephritis with uraemic convulsions. At that period it not uncommonly happened that sudden death, especially of a prominent person with rivals and enemies, was ascribed to poison. For example, the death of Henry Frederick, Prince of Wales, in 1612, which Norman Moore two hundred and seventy years later argued was due to typhoid fever, aroused this suspicion. This was also suggested in the case of Charles II, and, further, Thomas Short, one of the physicians attending His Majesty, is credited with this belief. According to *The History of my own Time* by Gilbert Burnet, Bishop of Salisbury, Short, who was suddenly taken ill and died in 1685, after drinking a large draught of "Wormwood wine in the house of a popish patient," told Lower, Millington, and other physicians that he believed that he himself had been poisoned because he had spoken so freely about the King's death.

A Review of the Pathological Evidence

Dr. Krumbhaar,¹ professor of pathology in the School of Medicine of Pennsylvania University, has recently un-

earthed and presented to the Library of the College of Physicians of Philadelphia two contemporary manuscripts bearing on the death of Charles II, and in describing them has taken the opportunity of reviewing the evidence. While freely quoting and agreeing with Crawford, he concludes that in modern terminology the post-mortem diagnosis would read: oedema of the brain, chronic fibrous pleurisy (right), hypertrophy of the heart, congestion of the liver, spleen, and kidneys, and that it demands but little imagination to picture an arteriolar nephrosclerosis or a chronic glomerulonephritis, which, if without much scarring, might easily have been overlooked a century and a half before the days of Bright, and that the king died from an exacerbation of renal insufficiency, alleviated by bleeding but aggravated by the cantharides used for blistering, the terminal "fits" being due to uraemia and not to cerebral haemorrhage. Wepfer's important clinico-pathological study of cerebral haemorrhage in 1658 as causing apoplexy was probably not known to the king's medical attendants.

ANNALS OF MEDICAL HISTORY

The first of the six main articles in the July instalment of the *Annals of Medical History*¹ is by Mr. William White of Los Angeles, and surveys the wide field of the social implications of the history of medicine in Great Britain between 1742 and 1867. This paper, read in January, 1937, to a seminar at the University of Southern California, is most conscientiously documented, and admittedly owes much to the writings of Sir D'Arcy Power. Dr. Shuman, also of Los Angeles, concludes his interesting account of the medical practitioners in South California. G. W. Corner of Rochester, the fourth of that name, analyses the representations of medical practitioners in the modern drama and speaks of the change from the politically philosophical practitioners of Ibsen and even Schnitzer to the dispassionate human beings in the hands of Howard and Kingsley. The character of E. L. Hakim in *The Talisman* is analysed by Dr. Tallmadge; the epidemic of small-pox in 1738 in Charlestown and inoculation form the subject of a paper by Dr. Waring of Charlestown, South Carolina; and Dr. Freeman sketches the history of geriatrics, a word introduced for the diseases of the aged by Nasher about twenty years ago.

One hundred years ago Thomas Joseph Pettigrew (1791-1865) published the first volume of his biographical work *Medical Portrait Gallery*, which in its time was as popular as it was indispensable. The fourth and final volume was completed in 1840. In 1838, too, appeared his "Account of the examination of the mummy of Pet-Maut-Joh-Mes." A Fellow of the Royal Society and one of the original three hundred Fellows of the Royal College of Surgeons of England, Pettigrew was keenly interested in Egyptology, as a surgeon and anatomist delighting above all in the technique of mummification. His fondness for demonstrating mummies to public audiences soon brought him the nickname of "Mummy Pettigrew," and inspired his contemporaries to outbursts of wit and excruciatingly bad verse.

The issue of *Nederlandsch Tijdschrift voor Geneeskunde*, the organ of the Dutch Medical Association, for October 1 is a Boerhaave number, and contains the following papers among others read before the congress held recently in commemoration of the bicentenary of Boerhaave's death: "Boerhaave's Influence on American Medicine," by Henry E. Sigerist; "Boerhaave and the Early Medical School at Edinburgh," by J. D. Comrie; "The Influence of Boerhaave's *Institutiones Medicae* on Modern Physiology," by J. Fulton; and "Boerhaave as a Botanist," by T. A. Sprague.

THE BLOOD PLATELET

It is over thirty years since Wright advanced the theory that the blood platelets are derived from the megakaryocytes, but recent reviews by A. Hittmair¹ and by L. M. Tocantins² indicate that, though this origin is accepted by the majority of haematologists, convincing evidence is still hard to find. The mechanism of the process is obscure, as the conditions in surviving preparations of marrow are abnormal, while megakaryocytes do not form platelets in tissue cultures. Some authors have postulated sudden explosive rupture of the megakaryocytes. More plausible theories are that fragmentation of the pseudopods produces platelets in the same way as the mammary epithelium degenerates into colostrum granules, or that the megakaryocytes exert a physico-chemical influence on the neighbouring fluid in the same way as the fibrocytes lay down collagen fibres in the intercellular spaces. Megakaryocytes are present not only in the bone marrow but also in the spleen and the lungs, and it is conceivable that the lungs are an important site of platelet production. Much interest has recently been taken in a group of leukaemia-like conditions variously described as leuco-erythroblastic anaemia,³ chronic non-leukaemic myelosis,⁴ megakaryocytic myelosis with osteosclerosis,⁵ and erythroleukaemia.⁶ The common factor in these conditions is the presence of excessive numbers of megakaryocytes not only in the bone marrow but also in myeloid foci in the spleen, the liver, and the glands. The blood platelets are not increased in numbers—in fact there is a haemorrhagic tendency—there is no accumulation of megakaryocytes in the lungs, and the disorder progresses to fibrosis of the bone marrow, encroachment on the marrow cavity by cancellous tissue, and increased density of the cortex of the bones. The giant cells are identical with those normally present in the marrow, to which the function of platelet formation has been attributed, but the sequence of events gives little support to Wright's hypothesis.

Whatever their origin, we must regard the platelets as a particulate secretion rather than as a cellular element of the blood. Not every particle in the blood stream is a platelet, and fragments of erythrocytes, leucocytes, fat droplets, parasites, and other structures have often been confused with them. This is one cause of the variety of views on their origin. Moreover the platelets are very labile, and their apparent number, size, and shape may be greatly modified by technical errors. The average number of platelets per cubic millimetre in healthy young adults is 250,000 in cutaneous blood, 300,000 in venous blood, and 350,000 in arterial blood. The very high normal values reported by some authors are the result of methods which break up the platelets, and figures above 500,000 are seldom, if ever, obtained in cutaneous blood in health. Platelets are often described as showing a dark central zone or chromomere and a clear peripheral zone or hyalomere, but this also is an artefact, for when platelets are rapidly fixed they present a diffuse and uniform granularity. Efforts to classify platelets by their size, shape, and staining reaction⁷ are to be viewed with suspicion.

The distribution of platelets through the circulating blood is irregular, and observers with the capillary microscope describe seeing schools of platelets, succeeded by periods when few or none are visible. When a vessel is injured platelets rapidly accumulate on the roughened surface and form the white thrombus from which the red thrombus grows down-stream. Agglutination of platelets and formation of thrombi can to a large extent be inhibited by the injection of heparin, which is now available in a form suitable for use in man.⁸ Coagulation of blood may be initiated or proceed in the presence of few or no platelets, as in the coagulation of lymph, and agglutination of platelets may take place independently of coagulation. The correlation between simple numerical changes in the platelets and the rate of coagulation of the blood is in fact low. Nevertheless it is generally agreed that the platelets play a part in initiating or accelerating the coagulation of blood. Only a small fraction of them are used up in the process, and the remainder play an even more important part in haemostasis by forming knots to which the fibrin filaments adhere. The clot then contracts, and the margins of the wound, which have already been brought into apposition by vascular constriction, are sealed together.

In essential thrombocytopenia—the purpura haemorrhagica of Werlhof—there has long been controversy whether the low level of platelets is due to diminished production or increased destruction. The symptoms improve dramatically after

¹ *Folia Haemat., Lpz.*, 1938, 59, 50.² *Medicine*, 1938, 17, 155.³ *Edinb. med. J.*, 1936, 43, 303.⁴ *Quart. J. Med.*, 1937, 30, 253.⁵ *J. Path. Bact.*, 1937, 45, 383.⁶ *Ibid.*, 1938, 47, 327.⁷ *Folia Haemat., Lpz.*, 1937, 58, 363.⁸ *J. Physiol.*, 1935, 92, 20.

splenectomy, but this may be equally well explained by assuming that the spleen inhibits the maturation of the platelets in the marrow or that it removes them from the circulation. If the work of Troland and Lee⁹ is confirmed, there will be an end to this controversy. They were able to extract a substance from the spleens of patients with essential thrombocytopenia which reduced the platelet count by 90 per cent. when injected into animals. No such "thrombocytopen" could be obtained from other tissues or from spleens removed for other diseases. The method employed for making the extracts was simple, and it is much to be hoped that others who have the opportunity to obtain material will speedily prove or disprove the claim. Experience has amply confirmed the suspicion that sedormid is a potent cause of purpura. A certain proportion of people either have or develop an idiosyncrasy to this drug, which manifests itself by an abrupt fall in the platelets and haemorrhagic purpura.¹⁰ The symptoms may be exceedingly severe, and there is no reason to doubt that they may prove fatal. The choice of hypnotics is so wide that there would seem to be no reason for prescribing a drug which has this alarming potentiality, and practitioners in this country would be wise to follow the example of their American colleagues and exclude sedormid from the list of approved remedies.

GOVERNMENT VERSUS CANCER

In announcing the Government's decision to make available modern facilities for the diagnosis and treatment of cancer in this country at the Council Dinner of the British Medical Association on November 8 Dr. Walter Elliot, the Minister of Health, said that in elaborating the details of the scheme he undertook to do his utmost to consult all the interests concerned—"local authorities, medical practitioners, research men." Later it was announced that Dr. Elliot was in negotiation to purchase £500,000 worth of radium for the treatment of cancer, and, according to a statement in the *Times*, the Eldorado Gold Mines, Ltd., at Port Hope, Ontario, have received an order from the British Government for 11 grammes of radium at a cost of about £200,000. That the Government has taken this important step is to be warmly welcomed by the medical profession, and it is much to be hoped that the Minister has fulfilled or is fulfilling his promise to consult those experts who alone are in a position to give him the best advice as to what could be expected from any scheme planned on the scale contemplated. Has, for example, sufficient cognizance been taken of the

developments in radiotherapy in other countries? It is the opinion of many distinguished workers abroad that in future radium will be used only for implantation into the actual growth, and that x rays will be employed for attack on those deeper growths which are inaccessible to direct implantation methods. This opinion requires the most careful examination before any irrevocable step is taken. Results obtained by expert and careful application of "bombs" containing 5 grammes of radium are encouraging enough to justify their use in the treatment of growths only a few centimetres below the surface of the skin. But for the deeper growths—as, for example, in the lung, stomach, and rectum—"bombs" containing as much as 20 grammes would be needed, and it is obvious that not many of these would be available at the present price of radium. Here it may be pertinent to remark that with the development of the radium mines in Canada it does not seem at all unlikely that within a few years the price of radium may be considerably less than it is now.

Coincident with this development in the mining of radium is the work started by Professor E. O. Lawrence in the University of California with the cyclotron, which has been described as an "atom smasher." Already in the U.S.A. twenty-two of these machines are in operation or are being built; several are under construction in the Scandinavian countries, and at least two of these will be used partly for medical and biological purposes. The two machines that are being built in this country at Cambridge and at Liverpool will be devoted largely to physical work and are not designed for use in medical treatment. We have already drawn attention in these columns¹ to the cyclotron and to the fact that the artificially radio-active substances produced by it have been given to patients suffering from myelocytic leukaemia, with successful results. A team of workers in the University of California is now actively engaged in investigating the possibility of substituting neutrons for radium in the treatment of cancer. Neutrons have been shown to be at least three times more lethal to malignant cells than an equal dose of x rays. It is clear, then, that the production of artificially radio-active substances and of neutrons by the cyclotron in amounts that make them easily available for therapeutic purposes is of the highest importance. The question immediately arises: Has the Minister of Health gone into this question and discussed with expert medical advisers the possibility (we would say desirability) of developing a cyclotron unit in this country exclusively for medical purposes? Is it indeed too late to suggest that say one-tenth of the £500,000 might be set

⁹ *Johns Hopk. Hosp. Bull.*, 1938, 62, 85.
¹⁰ *Lancet*, 1938, 2, 305.

¹ *British Medical Journal*, 1938, 2, 25.

aside for this end? While radium is needed and of great value in the treatment of cancer, it is essential that other methods of treating this disease—and especially the newest methods—should not be neglected. A cyclotron unit for medical research is urgently needed, and there are men with the necessary technical training and experience to operate it. We would suggest, too, that if the building of this apparatus should come to form part of the Government's cancer scheme, then research with it should be under the guidance of some such authoritative body as the Medical Research Council. It is essential that research be not neglected.

THE TREND OF URBAN MORTALITY

A prolonged period of economic depression, rising to a peak in the years 1929–33 and intense enough to affect directly or indirectly all the activities of the country, might well be expected to show its effect on the mortality statistics, especially in what have been called the depressed areas. Snatch samples of morbidity and mortality statistics can readily be adduced to support this view, but before sound generalizations can be made it is necessary to examine evidence collected on as wide a basis as possible and to institute a comparison with standards uninfluenced by local or chance circumstances. This, in fact, was the object of the research undertaken the results of which are embodied in No. 86 of the "Reports" series just issued by the Ministry of Health.¹ In his prefatory note as Chief Medical Officer Sir Arthur MacNalty is able to quote (and we assume with some degree of satisfaction) that "there is no evidence from the trend of mortality rates from all causes of death that the health of the population of the 'depressed areas' . . . has been unfavourably affected by the economic depression," and he appears justified in adding that this conclusion is "strong testimony of the success of national and local efforts to mitigate evils the magnitude of which needs no new comment." Dr. Lewis-Faning, referring to the investigations in America and elsewhere on trade depression as a factor influencing national health, explains the limitations of the statistical method in examining questions of this kind. Records of morbidity that took into account the non-fatal ailments—especially of women and children—would appear to have more value than mortality statistics, but unfortunately these are not available in a form or in quantity suitable for a wide-scale comparison, and it must be remembered that the trend of local statistics may be overshadowed by some nation-wide influence—for example, the upward rise of the general mortality rate from the south northwards. As "depressed areas" Dr. Lewis-Faning has included the counties and county boroughs of Lancashire, Cheshire, Northumberland, Durham, Glamorgan,

Monmouth, Brecknock, and Carmarthen, a sufficiently wide and representative group. For contrast, a selection was made of some sixteen county boroughs, including Lincoln and southwards, together with the administrative county of London, which were deemed "prosperous," since their unemployment rate was below the mean for boroughs generally. So far as the "depressed areas" are concerned the analysis shows that there has been a decline in the mortality rate at all ages during the past twenty years, and that these rates were lower in 1920–2 than in 1911–13, and still lower in 1930–2 than in 1920–2; but these rates always have been, and still are, higher than those for the country generally. With regard to the "prosperous areas," although in this connexion the term "contrast areas" would be better, mortality has declined in all cases during the past two decades, and, with four exceptions, has been consistently lower than for the whole country. In the northern group the boroughs of Lancashire are better relatively to England and Wales, those of Durham and South Wales are somewhat worse, while in the southern group the relative position has remained fairly stationary. The third and fourth sections of the report take account of annual death rates in age-groups for the years 1911–34, and by means of tables and graphs show that, although there has been occasional excess mortality among males in certain depressed areas, this excess is not related to the period 1929–33; on the contrary, these counties have kept pace with the country as a whole as regards the decline in general male mortality, and for females the results are very similar. In both groups exceptional areas are to be found—that is, "black spots" in the "prosperous" group and "white spots" in the "depressed" group—which when considered in their proper bearing (Table 12) lend no support to the theory of causal relation between depression and excess mortality, and at all events the absolute rates have steadily declined. The general conclusion reached is that excess mortality, where it occurred, was not a feature peculiar to the years of depression but has been apparent for at least the past twenty years. This is described as "the shadow of the picture," and it goes to show that these local heavy mortality rates are due to some more deeply rooted evil and possibly involve genuine geographical and racial factors. It is admitted that the specific problem set has not been solved, but the investigation has at least disposed of the unwarranted suggestion that unfavourable features of our mortality experience have been slurred over or ignored in official publications.

TRANSFUSION OF LEUCOCYTES

The virtue of the ordinary transfusion of blood lies largely in the addition of erythrocytes to the recipient's circulation; as a result there is more haemoglobin available for carrying oxygen to the tissues. To a less extent the other elements in the transfused blood—leucocytes, platelets, various immune bodies, and complement—may be of use; in the case of thrombocytopenic purpura the increase in platelets after a blood

¹ *A Study of the Trend of Mortality Rates in Urban Communities of England and Wales with Special Reference to "Depressed Areas."* By E. Lewis-Faning, Ph.D., of the Medical Research Council's Statistical Staff. H.M. Stationery Office. 1s.

transfusion may raise their numbers above the critical level below which bleeding is apt to occur. The addition of leucocytes (neutrophil polymorphonuclear cells) to a patient's blood stream might prove beneficial in cases of extreme neutropenia due to toxic derangement of the normal marrow leucopoiesis—for example, primary or secondary agranulocytosis. Compatibility of white cells has not been taken into consideration in ordinary blood transfusion, but there is evidence that direct agglutination of these cells may occur; this factor would have to be avoided in the use of a donor's leucocytes as a therapeutic agent. The relatively small number of leucocytes in whole blood compared with erythrocytes and even platelets militates against their use in practical therapeutics: a very large volume of whole blood would be required to increase significantly the leucocytes in the recipient's blood stream. Further, the duration of life of a transfused leucocyte is much less than that of a red blood cell. To overcome these drawbacks J. Hanausck¹ has devised an easy technique for obtaining leucocytes in concentrated suspension from citrated blood. The method depends on separation by fractional sedimentation, and the apparatus required is very simple. Working with horses' blood he was able to obtain large quantities of leucocytes for laboratory experiments. Separation of leucocytes from human blood could be accomplished in a similar way and form a supply for transfusion purposes in the types of cases already indicated.

NEW INTERNATIONAL STANDARD FOR VITAMIN B₁

It is announced that the first international standard for vitamin B₁, which consisted of an adsorbate of the antineuritic vitamin, made from rice polishings, on fullers' earth, has now been replaced by a preparation of crystalline vitamin B₁ hydrochloride. In recent years progress in the study of the antineuritic vitamin has been rapid, and this change in the form of the international standard has been made possible by the synthetic preparation of the vitamin in pure crystalline form. Through the generosity of four manufacturers an adequate quantity of the new crystalline material was placed at the disposal of the National Institute for Medical Research, Hampstead, to enable a new standard to be prepared consisting of the pure crystalline substance. Extensive international investigations of the properties of this material and, in particular, the determination of its potency in terms of the original international standard by a variety of methods have now been completed, and the members of the International Conference on Vitamin Standardization have unanimously recommended that the sample be adopted as the Second International Standard for Vitamin B₁, and that the international unit be defined as the antineuritic activity of 3 microgrammes of the international standard preparation. This recommendation has been adopted by the Permanent Commission on Biological Standardization of the Health Organization of the

League of Nations. As in the case of the other international vitamin standards, the new standard for vitamin B₁ is held, on behalf of the Health Organization of the League of Nations, at the National Institute for Medical Research, Hampstead, and is distributed therefrom to national control centres established in other countries for local distribution to laboratories, institutes, and research workers; and to workers resident in countries in which the establishment of national control centres has not yet been completed. With regard to the supply of the new standard for vitamin B₁ to those requiring it in the United Kingdom, samples have already been sent to the laboratories, institutes, and research workers who have hitherto received the standard adsorption product. Others requiring the standard are asked to make application to the Department of Biological Standards, National Institute for Medical Research, Hampstead, N.W.3.

GRENZ RAYS

For two generations the growing-point of physics has been concerned with the effects of electromagnetic radiations, and in this growth the use of such radiations in medicine has played a not inconsiderable part. The two main gaps in the electromagnetic spectrum—between "hard" x rays and gamma rays, and between the short ultra-violet and "soft" x rays—are in process of closure: the former by the development of super-voltage therapy on the medical side and by the study of atomic disintegration on the physical side, and the latter by the study of the Grenz rays. Grenz rays are very soft x rays, generated at a few thousand volts and with a wave-length of 1 to 3 A.U. Their physical characteristics have been investigated chiefly by Rajewsky and his associates in Frankfort; they have shown that it is in the region of the Grenz rays that the Bunsen-Roscoe law (intensity \times time = a constant) becomes invalid, and by calculating the energies of beams of different wave-length they demonstrated¹ that the skin erythema produced by x rays occurs by absorption at a depth of 0.12 mm. The physical data necessary for the accurate application of Grenz rays in medicine have been summarized by Z. A. Leitner: the quality of the beam is expressed in terms of its absorption in air or aluminium and the dose is measured in roentgens by a thimble-chamber ionization instrument. The rays are so soft that a beam at 4 kV is reduced to half its intensity by passing through 10 cm. of air, and at 8 kV to one-fifth by 2 mm. of skin. The almost complete absorption of the rays in the skin makes them particularly suitable for use in dermatological conditions, and the rapid recovery of the skin after therapeutic doses allows repeated courses of treatment in complete safety. The first-degree erythema dose is of the order of 2,000 r, but ten times this amount has been given in a short period without any permanent damage. The use of Grenz rays, however, is not confined to dermatology, since it is believed that their absorp-

¹ *Ann. Inst. Pasteur*, 1937, 59, 652.

² *Strahlentherapie*, 1932, 45, 398.
Brit. J. Radiol., 1938, 11, 586.

tion in the skin brings about general metabolic changes, and that Grenz-ray therapy thus influences constitutional diseases such as rheumatism, asthma, etc. The fact that these beneficial effects are generally said to occur by way of an influence on the vegetative nerve-endings in the skin indicates how slender is their scientific basis. In rheumatism, asthma, and cancer Scott³ has claimed good results by irradiation of indifferent areas of the body with medium-hard x rays, and if these results were generally confirmed the mechanism is probably similar to that claimed for Grenz rays. There would certainly appear to be a case for a controlled investigation of the effects of Grenz rays in constitutional diseases; the comparison of a group of chronic rheumatics treated with Grenz rays with a group exposed to sunlight and fresh air would be an interesting experiment.

PERSPIRATION AND SUNBURN

Perhaps the most important part played by perspiration is in the regulation of body temperature. That the sweat glands can actively secrete certain constituents of the blood is well illustrated in those miners who lose such large quantities of sodium chloride in the sweat that a condition of hypochloræmia is established, causing miners' cramp, a syndrome easily prevented by drinking water containing salt. The factors controlling the chemical composition of human sweat are not clear: sodium chloride, urea, uric acid, lactic acid, ammonia, sugar, creatinine and creatine (very slight traces), amino-acids, lipoids, and even protein have been found in it; in nephritis the excretion of urea in it is increased. That there are in sweat some as yet unknown substances is suggested by recent work by Crew and Whittle.⁴ These authors set out to test whether there is any justification for a commonly held view that human skin is less readily sunburnt if perspiring freely than if it is dry. Crew had previously demonstrated that a millimetre film of sweat absorbs slightly at a wave-length of 3300 A.U., very appreciably at 2900 A.U., and almost completely at 2700 A.U. It has now been shown that the most effective region of solar radiation from the point of view of sunburn on human skin lies between 3140 A.U. and 2960 A.U., with the maximum at about 3040 A.U.; limits of the visible spectrum at the violet end are 3800 A.U. Such data suggest that sweat would in favourable conditions act as a barrier to the rays most effective in producing erythema. Experiments were carried out on healthy male subjects in whom sweating was stimulated by such means as a hot bath or running half a mile when very warmly dressed. The sweat was obtained from the forehead, the first excretion being wiped off; as much as 5 c.cm. at a time could thus be obtained in a tube. The source of radiation was a quartz mercury-vapour water-cooled Kromayer lamp, a cell containing human sweat being interposed between the lamp and the skin. Exposures were made on the inner surface of the forearm or the thigh; the time of exposure varied from one to two minutes. It

was found that sweat does provide some protection against the production of erythema and that a film 0.2 mm. thick gives a just detectable but definite screening effect. That the effect was not entirely due to suspended matter was shown by obtaining it after preliminary passage of the sweat through ordinary filter paper or a Chamberland candle. Preliminary ether extraction of the sweat removed a good deal of its absorptive power and the fatty bodies present in the ether extract possessed absorptive power for the erythema-producing rays. Control experiments with water and physiological saline were negative. Using spectrophotometric methods it was further demonstrated that a 1-mm. film of natural sweat transmits only about 40 per cent. of the radiation at wave-length 3500 A.U. and about 6 per cent. at 2500 A.U., while filtered sweat is considerably more transparent at 3500 A.U. (78 per cent.) but only slightly more so at 2500 A.U. The fact that in prolonged sweating there occur a considerable secretion of natural lipoids and a deposition of dissolved substances freed from (evaporated) water makes it almost certain that the degree of protection afforded is greater than indicated by the *in vitro* experiments, as they may be called. Explanations of the phenomena in terms of the absorptive power of the known constituents of sweat were not very satisfying; they would account for only a negligible fraction of the demonstrable absorptive power of the sweat as a whole. Even cholesterol, the absorptive curve of which bears some resemblance to that of sweat, could not account for the observed results. Iron has been suggested as reducing the sensitivity of the skin to sunburn, but the amount of iron in human sweat (determined spectroscopically) is not more than 0.0005 per cent. Examination of the transmissivity of human epidermis in the relevant range of wave-lengths yielded a curve similar to that obtained with sweat, and hence it is suggested that a single substance is perhaps present in both epidermis and sweat which is highly absorbent for this wave region. The nature of such a substance is at present unknown, but it would appear reasonable to proceed with these highly interesting experiments and use other constituents in the body—for example, serum and tissue extracts, particularly nerve and vessel walls.

DETERMINATION OF THE CIRCULATION TIME

Investigation of the dynamics of heart failure in man has been possible in the last decade by the development of many methods for the determination of cardiac output, circulation time, and circulating blood volume. These three factors are closely interrelated, and it is obvious that, with other conditions remaining the same, output will vary inversely with the circulation time and directly with the volume of blood circulating. Whereas the output in congestive heart failure is generally, but not constantly, reduced, it is rare for the velocity of the flow of blood to remain unaltered, and it is used as a more reliable and also a more delicate index of circulatory change. There is also the advantage

³ *Proc. roy. Soc. Med.*, 1935, 28, 684.

⁴ *J. Physiol.*, 1938, 93, 335.

that it is much more easily measured than the cardiac output. The blood velocity has, as a rule, been measured from the arm to the pulmonary capillaries, or from the arm to the neck or tongue, the former method being suitable only in cases of right heart failure. Since 1927, when Blumgart and his collaborators devised a method with a radium preparation, a large number of substances have been employed. All have the property of producing some form of stimulation at some distant point after injection into the circulation, the effects of which can be quickly recognized. They fall into two main groups: first those which are given off in the lungs and are noticeable in the breath—these measure the arm-to-lung circulation time, which is reduced in right heart failure; and, secondly, those which pass through the lungs into the left heart and systemic arteries and can be tasted on reaching the tongue, or, as in the case of the sodium cyanide method, stimulate respiration. With the second group left heart failure with engorgement of the lungs can be estimated. The normal circulation rate varies according to the method employed, and to a still greater extent from one individual to another, though in the same individual under basal conditions the same method gives fairly constant results. A disadvantage of most methods is that they are subjective—that is, the end-point depends upon the subject himself recognizing, and signalling his recognition of, the stimulus; and, with some, unpleasant effects are produced—for example, severe headache with the histaminic method. Recently paraldehyde has been used by S. Candel¹ to determine the arm-lung circulation time, 1.4 c.cm. being injected into an antecubital vein and a sharp cough denoting its arrival in the pulmonary capillaries. In favour of this are the sharp and objective end-point (the cough) and the fact that paraldehyde is convenient to use, requiring no sterilization. Against it are certain unpleasant reactions such as transient dizziness or hypnosis and the severity of the cough, which may last three minutes and is likely to be resented by a dyspnoeic patient. As a valuable and relatively simple way of making a differential diagnosis of cardiac failure and for estimating variations in the degree of failure, measurement of the rate of circulation will probably come into wider favour, but the ideal method has yet to be found.

SITE OF ACTION OF DIGITALIS

Although the value of digitalis in some forms of cardiac disease has never been disputed, the precise indications for its administration are not so well established, and how it works is a matter on which there is still less agreement. Thus, while the effect on heart failure with auricular fibrillation is so conspicuous that no one would question it, doubts have been expressed as to its beneficial action on fibrillation without failure and on failure with normal rhythm. It has been held for a long time that digitalis acts either on the conducting tissues, the depression of which slows the heart and explains the special action in auricular fibrillation, or directly on the

muscle, increasing its efficiency—that is, the contractile power in relation to oxygen consumed. A newer view is proposed by L. N. Katz, M. Mendlowitz, and H. A. Kaplan,¹ who hold that the action of digitalis on the human heart can be adequately explained as secondary to the effects on the peripheral circulation. The latter includes vasoconstriction of systemic and pulmonary arteries and of systemic veins; the venous return is also diminished by constriction of the blood vessels of the liver. In view of these and other extracardiac changes Katz and his co-workers reject the results of experiments in which the heart-lung preparation and the heart-lung spirometer are used, and believe that observations on the isolated heart only are free from error. But such observations should be made in conditions as nearly natural as possible. For this reason experiments on strips or fragments of muscle have a limited value, especially in relation to the failing heart. Thus the demonstration by R. N. Chopra and N. N. Das² that strophanthin and related drugs inhibit the rate of pulsation in fragments of heart muscle from young chick embryos (which they chose as being free from all nerve tissue) is important as indicating a direct action on heart muscle, but does not solve the problem of whether or not this is responsible for the therapeutic effects. Katz and his co-workers, using a method similar to that of the heart-lung preparation, except that an artificial resistance replaces the pulmonary circulation, found that both before and after cardiac failure had developed digitalis produced no significant change in size of heart, flow of blood, work, or oxygen consumption until a toxic effect on conduction appeared. In the failing heart both work and oxygen consumption decreased, mechanical efficiency remaining unchanged, while if the work was kept constant no change in oxygen consumption followed, despite a progressive increase in the size of the heart and in venous pressure. The conclusion is that digitalis has no significant action on contractility in the isolated heart, either with or without failure. These results show that there is room for further experimental work on digitalis and for a revision of ideas on the way it acts; but a sweeping conclusion from such experiments would be premature.

¹ *Amer. Heart J.*, 1938, 16, 149.

² *Indian J. med. Res.*, 1938, 26, 271.

On November 16 a dinner was given at the Athenaeum in honour of Sir Richard Gregory, F.R.S., who is retiring from the editorship of *Nature*, with which he has been closely associated for forty-five years, securing for it a position in scientific literature not equalled by any other similar periodical. During the last few years the columns of *Nature* have increasingly emphasized the responsibility of scientists to society, which culminated this year in the formation of a new division of the British Association to deal with the social and international relations of science. Sir Richard Gregory was chosen as the division's first chairman. This week he left for the United States, where he is to deliver on December 8 the Elihu Root lecture at the Carnegie Institution of Washington on "Cultural Contacts of Science."

with adhesive strapping. Should recurrence take place, operative retention by the use of sutures uniting the fragments will be necessary.

The treatment of fractures of the clavicle and scapula has been dealt with elsewhere in this series and does not require further description.

Injury to the Diaphragm

Laceration of the diaphragm of varying extent occurs in a small proportion of contusions of the chest. As a rule there are no distinctive symptoms in the early stages, and in radiographs the opacity in the lower chest caused by the abdominal contents herniated through the laceration in the diaphragm is mistaken for effusion or consolidation of the pulmonary tissue. At a later stage symptoms such as continued but indefinite indigestion or acute pain in the lower chest or upper abdomen, often associated with vomiting due to partial strangulation of the hernial contents, result in investigation by barium meal and radiographs, which make the diagnosis obvious.

The treatment is operative, and the prognosis, if strangulation has not occurred, is good. For traumatic diaphragmatic hernia approach through the chest is more satisfactory than that obtained through the upper abdomen, since the laceration can be more easily exposed and separation of omentum and hollow viscera adherent within the chest is easier and safer.

II. PENETRATING WOUNDS OF THE CHEST

The essential differences between the non-penetrating and the penetrating wounds of the chest are the greater incidence of infection, the production of an "open pneumothorax," the increased frequency of cardiac wounds and the occasional presence of a retained missile. Where these factors are not concerned the treatment of such injuries is largely that of the non-penetrating type. In all cases in which there is a lacerated wound excision and suture should be carried out as soon as the general condition of the patient permits, in order to obviate the risks of infection.

Open Pneumothorax

The presence of a lacerated penetrating wound which permits the entrance and egress of air into and from the pleural cavity has a very serious effect upon the respiratory function. The opening should therefore be closed as soon as possible. When conditions do not permit of immediate excision of the wound and closure of the chest wall by suture the wound edges should be firmly drawn together and fixed by adhesive strapping so as to prevent the free interchange of air between the pleural cavity and the exterior. The "débridement" should be undertaken as soon as possible to prevent infection. Subsequent treatment will depend upon the occurrence or otherwise of infection.

Retained Missiles

The question of the removal of retained missiles will depend upon their nature. Bullets, revolver or rifle, and smooth missiles such as shrapnel balls, can generally be left during the early days and the necessity for their removal decided at a later date. When irregular missiles are retained it is probable that portions of clothing have been carried in ahead of them. In such cases infection is almost certain to occur, and the question of their removal is a much more urgent problem. As soon as

the general condition of the patient permits they should be removed after careful radiological localization.

Cardiac Wounds

Suspicion of cardiac injury should always be aroused when penetrating wounds are situated over the precordial area. A considerable degree of success has followed exploration and suture of stab wounds of the heart, and it is essential to recognize the symptoms of haemorrhage into the pericardium, on which the diagnosis is chiefly based. The effusion of blood into the pericardium causes increasing difficulty in cardiac action, a condition termed "cardiac tamponade." The three cardinal symptoms are: (1) muffling of heart sounds—so-called "silent heart"; (2) falling blood pressure; and (3) rising venous pressure.

It is important to recall that cerebral symptoms can result from haemorrhage into the pericardium. These symptoms may comprise stupor, generalized rigidity with muscular twitchings, and occasionally hemiplegia, and are caused by cerebral anoxaemia. When the chest injury is associated with a head injury considerable difficulty may be experienced in deciding whether the symptoms are caused by direct cerebral injury or not. In such cases radiography may be most helpful, as when there is cardiac tamponade the cardiac shadow is enlarged and is often associated with pleural haemorrhage.

Cardiac injuries require treatment as soon as the diagnosis is determined, and the pericardium should be opened and the cardiac wounds sutured.

Late Results of Chest Injuries

In contusions and penetrating wounds in which a haemothorax is not aspirated and full expansion of the lung not attained after a period of some months, there is a tendency for calcification to take place in the walls surrounding the encysted blood—that is, parietal and visceral pleura. As this will result in restricted mobility of the chest wall and diminished functional capacity of the lung, and the fluid contents may subsequently become infected months or years later, it is essential to remove all blood-stained effusion from the chest by aspiration and ensure full pulmonary expansion and function.

Apart from diaphragmatic hernia, there is another late sequel to chest contusion, especially when it has been severe and has caused damage to the bronchial wall—namely, bronchial stenosis. This may be partial or complete, and may result in pulmonary atelectasis, often associated with secondary infection, and require lobectomy or even total pneumonectomy.

Lastly, the retention of a foreign body which has caused no trouble for months or even years may result in the formation of a pulmonary abscess, and give rise to secondary bronchiectasis and repeated haemoptyses.

These conditions will require treatment according to accepted principles. The control of the whole period of observation by repeated x-ray examinations will not only enable the immediate treatment to be carried out on the right lines, but will in many cases prevent the establishment of changes that will only be apparent months or years later.

In conclusion it will be seen that in the treatment of chest injuries it is inadvisable to intervene surgically in the early stages unless the evidence for such intervention is definite, and, likewise, that in the majority of cases all that is required later is aspiration of the contents of the pleural cavity.

THE HEALTH OF AFRICA

RESEARCH SURVEY OF A CONTINENT

At a time when the question of African territories is beginning to loom in European politics the compilers of *An African Survey*¹ have rendered invaluable service to those responsible for or interested in the affairs of that continent. The enterprise was first suggested by General Smuts in his Rhodes Memorial Lecture in 1929, when he pleaded for a review of the extent to which modern knowledge is being applied to African problems. An African Research Committee was formed under the auspices of the Royal Institute of International Affairs, with Lord Lothian as chairman, funds were subscribed by the Carnegie Corporation and the Rhodes Trustees, and Lord Hailey, who has been for thirty years a distinguished administrator in India, was appointed director.

The survey, to which the term "monumental" is not misapplied—it runs to nearly 1,700 pages—has occupied Lord Hailey and his helpers for nearly five years. It is only Africa south of the Sahara which has been taken; in consequence Abyssinia and the Sudan are not included. The principal attention has been directed to the Union of South Africa and the British, French, and Belgian colonies and mandated territories. The survey opens by describing the physical background, the sparse population, the stocks of the African peoples, their seven hundred languages, and goes on to discuss their systems of government, of law and justice, of taxation; the problems of labour, of agriculture, of water supply, of transport and communications; and the educational facilities and economic development. It presents the continent, in the words of Lord Hailey, as "a living laboratory." It is more than a collection of facts; it is an attempt to review the extent to which modern knowledge is being applied to African problems, and, as regards the British colonies, it makes clear the need for closer co-ordination of local research activities and for more adequate help for research from the Imperial Government.

The Approach to Health Problems

The section dealing with health is itself a substantial volume. From the days of Livingstone onwards public attention and sympathy Africa-wards have been concentrated upon such diseases as leprosy, sleeping sickness, and malaria. Another approach is now being realized—namely, that which takes into account the factor of defective nutrition. Important as may be the influence of nutrition on health conditions in Europe, it does not exercise the same decisive effect as in Africa. Medical science in Africa, says the survey, must be increasingly concerned with the relation between nutrition and health.

Another point made is that the methods must be largely those of mass attack.

"Preventive treatment applied to certain African diseases, to be effective, must partake to some extent of the character of an operation, scientifically planned and humanely conducted, but military in its spirit and offensive, and in the thoroughness with which it establishes itself in the area it has occupied."

It is also considered necessary that, under scientific leadership, there should be a large body of assistants who must as far as possible be Africans and must have as complete a system of training as circumstances will permit.

The incidence of the principal diseases in Africa is described, beginning with nutritional deficiencies, which obtain in almost every territory. Tuberculosis, probably not largely prevalent in earlier times, is now widely

distributed, and in Africa as in Europe is associated with poverty and overcrowding. On the other hand, leprosy has been with the Africans from time immemorial. About half a million cases are known, and the actual number may not be less than one million. The history of venereal diseases is obscure, but syphilis appears to have been prevalent in East Africa before the European occupation.

Present Health Services

After touching on the work of international bodies, such as the Health Section of the League of Nations, with its studies of trypanosomiasis, malaria, and leprosy, and the International Health Division of the Rockefeller Foundation, with its survey of yellow fever, the survey goes on to give details of the organization of health services in the different countries, from the Union of South Africa, where private and hospital practice is fully developed and where compulsory health insurance for the European urban population is suggested, to the British colonial dependencies, where, since the reorganization of the Colonial Medical Service in 1934, each territory has its medical department controlled by a director.

In Tanganyika Territory and Kenya the medical departments are arranged in administrative, medical, and laboratory sections, and the medical department in Kenya has taken a large share in projects for the improvement of living conditions in native reserves. The policy of the department is to set up in each native district a health centre consisting of a hospital with a medical officer and European nursing sister, with a number of out-dispensaries. In Uganda the policy of establishing dispensaries in rural areas is being actively pursued.

The organization in French West Africa is typical of the French preference for centralized and clearly co-ordinated methods of administration. Each of the colonies has a head of the public health service directly responsible to the Governor, and under him a staff of European doctors, of whom the majority are military and have undergone a course in tropical diseases. The "auxiliary" (trained African) doctors are an important feature of the French system. Under the Belgian system there has been a greater development of unofficial organizations than in the British and French colonies, and the Belgians have concentrated on medical work in rural districts. The Congo is divided for administrative purposes into districts, each of which is subdivided into territories in charge of official or unofficial organizations.

Medical Education of Africans

The survey envisages the medical service as a pyramid, the base of which is formed by a large body of African subordinate staff (such as nurses, dressers, hospital orderlies), the apex by fully trained medical officers, and the central part by the African auxiliary doctors or medical aids. Financial, among other, reasons make it impossible to contemplate that extensions in medical or health services should be attained by a proportionate increase in the number of fully qualified medical men. That the British territories do not at present contemplate making provision for Africans to take a full medical degree is largely due to the acknowledged lack of the necessary facilities for pre-vocational education. Africans are now being trained as medical assistants at the South African Native College in the Union, at Yaba in Nigeria, and at Mulago in Uganda. This training at the South African Native College takes the form of a course lasting for three years, preceded by a preparatory year's training in science, and followed by a year's practical hospital and public health training at Durban. It is anticipated that some of these assistants will be available for service in 1940. The schools at Yaba and Mulago appear to contemplate that at some future date they will be equipped to train the fully qualified African practitioner, though at present they have a more limited aim.

¹ *An African Survey. A Study of Problems arising in Africa South of the Sahara.* By Lord Hailey, G.C.S.I., G.C.I.E. (Oxford University Press. 1938. 21s.)

French West Africa has a school of medicine for Africans at Dakar, its capital, which is described as probably the most successful and certainly the largest effort in Africa to provide a colonial medical and health service with adequate African assistance. Since its foundation the school has provided over 400 assistants with an acknowledged standard of proficiency. The Belgians have lately opened a medical school at Léopoldville in the Congo. The survey calls for an expansion of the cadre of locally trained medical assistants. France at Dakar has led the way.

Health Education and Policy

Health education has its own difficulties in Africa, but they are not due to that opposition to the application of modern medical science which arises from attachment to a recognized system based on different principles, like the Unani system of medicine of many Moslem people in the East. The most difficult problem does not lie in enforcing anti-epidemic measures, but in persuading Africans to adopt the recognized principles of hygiene as part of their social habit.

"Not all those who practise native medicine in Africa can be dismissed as witch doctors; many are much respected, and it is indeed possible that a study of the herbs used by some of them might add to the list of remedies, such as quinine, which the pharmacopoeia owes to primitive medicinal practices."

It is suggested that the native African dislikes the greater discipline and isolation of the British hospitals as compared with the French. On the other hand, the French appear to lose by the fact that many of their doctors, being on the military cadre, have little incentive to study African conditions, and that administrative policy limits the expansion of medical facilities by refusing to open dispensaries where they cannot be supervised by a French qualified medical man. The French rely largely on a system of medical centres with attached dispensaries and mobile medical units, the Belgians on intensive measures of attacking affected areas with a view to clearing them up before handing them over to the care of the normal medical and health services. In the Union and in British territories a less elastic system of hospitals and outlying dispensaries is favoured.

"There seems good reason to hold that the mass infliction of disease of the type existing in Africa demands more direct methods of attack than have hitherto been employed in British territories; that funds should be devoted to organizing intensive medical campaigns rather than to the perfecting of the hospital system; and that, if necessary, statutory powers should be taken to secure that persons suffering from disease should submit to the necessary medical treatment."

More than once Lord Hailey returns to this theme:

"... it is difficult not to desire to see in some of the British territories more evidence of the spirit which shows itself in a direct attack on the health problems of the people. It is not enough to multiply facilities, ... disease of the type which causes most mischief in Africa is generally a mass infliction, and must be attacked in the mass."

Artemus Ward in a well-known passage declared that though the African was his brother he was not his sister and his wife and his uncle, and several of his brothers and all his first wife's relations. Somehow the passage comes back to us when we turn from the activities which the survey presents to the lowering background—an Africa with perhaps more than half its people still beyond the reach of medical and health services, with sanitation in many areas non-existent, with helminthic diseases almost universal, with widespread neglect in many central villages of the sick, the aged, and the young. Little can be done to improve such conditions until the Africans themselves

are conscious of a need for betterment, or at least until the native authorities themselves are aware of their responsibilities.

PROBLEMS OF HUMAN CONGENITAL DISEASE

PROFESSOR J. B. S. HALDANE'S LECTURE

With Dr. ROBERT HUTCHISON presiding, the Lloyd Roberts Lecture was delivered at the Royal College of Physicians of London on November 17 by Professor J. B. S. HALDANE, F.R.S., who took as his subject, "Some Problems of Human Congenital Disease." Professor Haldane began by expressing his sense of the honour of addressing the College, and asked as a layman to be excused inevitable solecisms when treating a medical subject which he had approached through a study of inherited abnormalities in animals.

Nature and Nurture

A person was regarded as afflicted with congenital disease, said Professor Haldane, if he was born diseased or if in early life disease developed which was believed to have been wholly or mainly predetermined at the time of birth. Examples of the first class were congenital syphilis, congenital pyloric stenosis, and ichthyosis foetalis gravior; examples of the second were Huntington's chorea, which, although the average age of its development was approximately 35, was yet believed to be due to an abnormality existing in the patient at the time of birth, and hereditary optic atrophy, which again might develop over a great range of ages but was believed to be congenitally determined.

In the large majority of cases, however, it was necessary to deal with the interaction between nature and nurture, to use Galton's words. In some cases one of these factors was predominant, but in a considerable majority there was some doubt. For example, there might be a degree of natural immunity to syphilis, the onset of hereditary optic atrophy might be determined by environmental conditions, at least to some extent, and so on. As a geneticist his own primary interest was naturally in differences of nature, differences in the hereditary endowment of the individual, and the question arose how to draw a line between the two. Where experiment was possible an endeavour had been made to keep nature constant in one series and nurture in another, just as in an experiment on gases the temperature would first be kept constant and the pressure varied so as to determine Boyle's law and then the pressure constant and the temperature varied so as to determine Charles's law. It was possible in animal experiments to approximate to nurture in many ways: to see that the animals had the same food, were exposed to the same liability to infection, and so forth. The most difficult thing was to standardize the pre-natal development. For example, in many stocks of guinea-pigs extra toes were not uncommon, and it was found in a given line that polydactylism was much more frequent among the offspring of young mothers than of old. The converse problem was to keep nature constant—that is, to obtain a group of animals all of which had the same hereditary endowment and test them out in different environments. There were two methods of doing this: one by prolonged inbreeding and the other by obtaining a group of animals related to one another by vegetative reproduction only and not through the sexual process. Experiments on human beings were, of course, out of the question.

The cases first studied were those in which either nature or nurture appeared predominant—on the one hand hereditary diseases, and on the other hand infections, to

which most people were susceptible. After this the cases were studied in which nature and nurture were more evenly balanced—for example, in acute rheumatism and phthisis, in both of which a hereditary factor and an environmental factor might coexist.

The Hereditary Mechanism

Professor Haldane began by considering cases in which the hereditary mechanism was obvious or at least fairly clear. He instanced split hand and foot, sometimes called "lobster-claw," and showed a pedigree in which every affected individual was the child of an affected individual, the disease never skipping a generation. The affected individuals passed the disease on to approximately half of their progeny without regard to sex, fathers and mothers transmitting equally to their sons and daughters. He also showed a pedigree of pre-senile cataract, and mentioned that Harman, in describing such a pedigree, had referred to a child who at the age of 2 years was practically blind, whereas the father was able to do unskilled work, and only on ophthalmological examination was a small cataract discovered.

A relatively trifling defect shown in the pedigree was short fingers, handed down by persons abnormal in this respect to approximately one-half their progeny. But there was one interesting exception. Two first cousins, both of them carrying the abnormal gene, married, and in addition to a daughter who had short fingers had another daughter who had no fingers or toes at all and showed other gross skeletal abnormalities. It was extremely probable that in such a case the child had received an abnormal gene from both parents.

The lecturer went on to make an analogy, for the crudity of which he apologized. Let it be supposed that a child inherited one eye from each parent. In that case one-half the children of one-eyed persons would themselves be one-eyed. But if two one-eyed persons married approximately one-quarter of their children would be completely eyeless. The analogy, though crude, had some justification. The genes responsible for hereditary differences were organs within the nucleus of a cell. Each gene appeared to control a specific function rather than a structure, but, unlike the organs in the body as a whole, they reproduced themselves directly—that is to say, when a cell divided the new genes were formed by a process which might be regarded as division or, as copying, according to taste. It might at once be questioned that, if this was the whole story, Adam and Eve must have suffered from a large variety of congenital abnormalities, being reservoirs of every conceivable defect that had shown itself in their offspring. There were no medical reports of the patriarchs, but they appeared to have enjoyed longer life than would be probable on that hypothesis. As a matter of fact, when these pedigrees of dominance were traced backwards the appearance of an abnormal individual from two normal parents was constantly found.

Occurrence of Mutation

The process by which new genes originated was called "mutation," of the nature of which extremely little was known. It might represent a failure to keep a normal gene in cell division or a change in a normal gene between cell divisions. The frequency of mutation could be increased some hundreds of times by means of x rays, but how to diminish its frequency was not known. Therefore it might be assumed that if the most extreme eugenic measures were taken with regard to the carriers of such abnormalities, although the number would be greatly diminished, they could not be completely abolished. Imagine—another crude analogy—what would happen if the kidneys were inherited one from each parent as he had supposed eyes to be inherited. Suppose that

1 per cent. of people had only one kidney and that this defect was handed down to half the offspring. Such a condition would be noticed relatively rarely. There would be a slightly greater tendency for people to die of kidney disease in later life, but the abnormality would largely go undetected. But when two persons with one kidney married one-quarter of their children would have no kidneys at all, and therefore would not live.

Professor Haldane mentioned a case of juvenile amaurotic idiocy. The child was normal until 6, then lost the sight, and about the age of 10 became idiotic. This was not in the ordinary sense a hereditary disease at all. It could not be handed down from parent to offspring, because the afflicted person almost invariably died before reproducing. He showed the pedigree of two families in which this condition appeared. In one family three out of five siblings were affected; in the other, one out of six. The parents of the two families were related to one another, but, what was more important, the husbands and wives in each case were cousins. It seemed likely that a recessive gene was handed down from one ancestor to the two different lines of the man and his wife, and on marriage a number of their children had an abnormality due to the presence of two abnormal genes.

Among other conditions which appeared to be so determined were albinism, haematoporphyria, and alkaptonuria. A more serious condition had been described in recent years in the shape of phenylketonuria, and every individual so afflicted had been a mental defective. This was an example of a metabolic disease associated with mental defect, probably due to a recessive gene.

Sex-linked Inheritance

Professor Haldane reminded his audience of the facts ascertained with regard to chromosomes and the different endowment of the sexes in this respect. He then mentioned as an example of a defect banded down through the male line the famous instance of the Lambert family, which suffered from ichthyosis hystrix gravior. The members of this family had a scaly coat which was said to moult once or twice a year. The first of these Lamberts was one of a number of normal children of normal parents. He had apparently six sons, one of whom handed down the abnormality to two sons but to no daughters, and so this fantastic pedigree continued in the male line for more than a century. Abnormalities inherited in that manner were extremely rare.

His next pedigree related to a history of colour-blindness of familial type, the abnormality occurring in males and being handed down through females, themselves apparently normal. The process was believed to be as follows: a man had an abnormal X-chromosome which rendered him colour-blind, and this defect he handed down to none of his sons but to all his daughters, who transmitted it to their progeny.

A far more serious disease of the same character was haemophilia, which had occurred among the descendants of Queen Victoria. One of her sons, Prince Leopold, was a sufferer, and handed the abnormality down to one or two of his daughters. The remaining haemophiliacs derived from two of Queen Victoria's daughters. One granddaughter married the last Tsar of Russia, and the Tsarevitch had haemophilia; another married the last King of Spain, and their son, too, had the same condition. Edward VII was not a haemophiliac and could not have transmitted haemophilia or any tendency thereto to his descendants. The fact that Queen Victoria was a carrier of haemophilia did not imply that there was any trace of that disease in the present royal family. When an attempt was made to trace the pedigree further back no sign of haemophilia was found among Queen Victoria's ancestors or collaterals, and it was evident that the condition owed its origin in her to mutation.

Finally, there was incomplete sex linkage as seen in certain pedigrees of retinitis pigmentosa, in which a man receiving a gene from his mother would hand it down predominantly to his daughters and to only a small proportion of his sons. There would occasionally be an affected son and an unaffected daughter. A case of more medical interest was that of hereditary fragility of bone. Here the presence of blue sclerotics gave some indication in the pedigree, but little idea could be formed as to the conditions which the sufferer from that diathesis would develop, whether fragility of the bones or otosclerosis. He showed also a pedigree of cases of acholuric jaundice. Here again a definite diathesis was transmitted—namely, corpuscular fragility. But there were many cases of irregular inheritance where a disease or abnormality ran in a family and yet nothing could be said as to whether a given individual, apparently normal, would or would not transmit it to a proportion of his or her children. This was particularly serious in such a condition as Huntington's chorea, where the disease might not develop until the end of the reproductive period, by which time a number of potential choreics, many of them doomed to insanity, would have been brought into the world.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

THE ANNUAL DINNER

The annual dinner of the Society of Medical Officers of Health was held on November 18 under the presidency of Dr. ELWIN H. T. NASH. The guests included the President of the Royal College of Physicians (Dr. Robert Hutchison), the President of the Royal College of Surgeons (Mr. Hugh Lett), the President of the British College of Obstetricians and Gynaecologists (Dr. W. Fletcher Shaw), the President of the Royal Society of Medicine (Sir Gilling Ball), the Chairman of Council of the British Medical Association (Sir Kaye Le Fleming), the Secretary of the Ministry of Health (Sir George Chrystal), the Chief Medical Officer of the Ministry of Health and Board of Education (Sir Arthur MacNalty), and many representatives of bodies associated with the public health. The Mayors of Kensington and of Heston and Isleworth were also present.

Preventive and Curative Medicine

Dr. ROBERT HUTCHISON, in proposing "The Society of Medical Officers of Health," said he felt strongly that the more the members of the two great divisions of medicine—the preventive and the curative—saw of each other the better. There was apt to be unnecessary friction between them. General practitioners sometimes regarded the medical officer of health as an interfering person, and, as Dr. Johnson remarked, "physicians do not love intruders." It was all the more necessary for the two to cultivate friendly relations, and he wished every medical officer of health was a regular attendant at meetings of local medical societies and of the British Medical Association. It must be confessed that in the fight against disease the preventive side had had more victories to its credit than the curative. The recent developments in chemotherapy, however, had given fresh hope of new cures to come, while as regards ordinary environmental hygiene he doubted whether much could be added to the laurels of those concerned when existing schemes of slum clearance and the like had been completed and administration in backward districts levelled up. Largely by the efforts of preventive medicine mortality had been reduced and the expectation of life increased, but there remained an enormous and even an increasing amount of morbidity. Much of this was due to functional diseases of psychological origin, and if these were to be prevented, preventive medicine in future must widen its scope to deal with mental and moral as well as

material environment. Health, after all, was a state of perfect adjustment between the environment and the organism. This adjustment had largely been effected on the physical side, but on the mental side it was increasingly difficult with the rush of present-day living, the anxieties, uncertainties, and perplexities, which tended to undermine health and to render not worth living the longer years that preventive medicine had given us. To deal with these factors, however, was a task for statesmen and philosophers. He rejoiced to see the Society, now nearly an octogenarian, continuing to grow in influence and ability. In coupling the toast with the name of Dr. Nash he referred to the president's initiative and energy as a medical officer of health and the usefulness of his contributions to the literature of the subject. Dr. Nash had now retired from active work, and they would wish him many happy years of leisure.

The PRESIDENT, in his response to the toast, said also that the relations between the medical officer of health and the general practitioner had not always in the past been happy. His own first chief used to boast that he knew he was a success because he had quarrelled with every general practitioner in his administrative area. Clinicians and administrators would have to become more and more associated as the years went by. The next ten years would see amazing changes in the relations between the medical officer of health and clinical practitioners of all kinds. He hoped that with the development of local authorities' hospitals there would be no tendency to bring about the disappearance of the general practitioner, for nothing could really replace a good general practitioner. He himself was extremely happy to have started his career in general practice.

The toast of "The Guests" was proposed in a happy speech by Dr. J. GREENWOOD WILSON, M.O.H. for Cardiff, and a response was made by Sir GEORGE CHRYSAL, who said that, like his predecessors at similar gatherings, he wished to state how much the officers of the Ministry valued and admired the work of those engaged in local health administration. During the three years he had been in his present position he had witnessed a great increase in such administration and its responsibilities and labours. They were all realizing better than they could have done at the time what immense changes the Act of 1929 brought about and what readjustments of social and public health policy were made necessary. Further work would arise with the coming into concrete form of the new proposals with regard to cancer. Referring to a national emergency, Sir George Chrystal said he did not share the general anticipation that the requirements of national emergency would mean a diversion of energy and money from the things in which they were permanently interested. The necessity for organizing emergency measures had a good side even for the works of peace. It meant a national stocktaking, in the course of which many shortcomings would be made good and notable additions to the permanent equipment of public health services secured. He also announced that the Ministry was to give financial assistance—"a notable Christmas box"—to the National Council for Health Education.

Dr. R. VEITCH CLARK proposed the toast of those members of the Society who have during the year received honours, and coupled it with the name of Sir WILLIAM SAVAGE, who made a brief reply in a vein of personal reminiscence.

J. J. J. de Jong (*Nederl. Tijdschr. Geneesk.*, 1938, 82, 5122) records the cases of two diabetic women, aged 23 and 57 respectively, who proved refractory to treatment by insulin. In view of the close resemblance of their blood sugar curves to those of acromegalic patients the resistance to insulin was thought to be of pituitary origin. In one patient the pituitary region was irradiated by x rays; the resistance to insulin disappeared and was replaced by a normal response.

BRITISH HEALTH RESORTS ASSOCIATION

The annual meeting of the British Health Resorts Association was held in London on November 18 at the house of the Royal Institute of Public Health and Hygiene. The chair was taken by the president of the association, Lord MESTON, who spoke with appreciation of the work of the Executive and the Medical Advisory Committee, and especially of the outstanding services of the general secretary, Dr. Alfred Cox.

The Year's Work

Lieutenant-Colonel W. BYAM, chairman of the council, gave a more detailed survey of the work of the year. The chief event, he said, had been the taking over of the handbook *British Health Resorts* by the association, thanks to the financial guarantees of certain friends. It was hoped next year to distribute 25,000 copies of this handbook to members of the medical profession, and, if enough support were forthcoming in the following year, to have a copy of the book on the table of every practising doctor in the kingdom.

The association, Colonel Byam continued, had previously drawn attention to the absence of the subjects of medical climatology and hydrology from the teaching of the universities; therefore it was all the more gratifying to record that during the year Leeds University had appointed Dr. Geoffrey Holmes as lecturer in medical hydrology. A beginning had also been made in postgraduate teaching under the auspices of the Fellowship of Medicine at Bath, Buxton, and Harrogate. By this means medical men could be taught what was valuable at the spas, and at the same time resident doctors could be stimulated to do greater work on such an obstinate community health problem as rheumatic diseases. The Medical Advisory Committee was in consultation with the Cardiac Society with a view to considering the possibility of some British spa laying itself out to deal with disorders of the circulation. He rejoiced that the B.H.R.A. was helping to build up a community feeling in the spa world; it was hoped to help the spas and health resorts to develop a comprehensive service which would deserve recognition by the Government. By arrangement with the British Spas Federation the Medical Advisory Committee had carried out a series of "visitations" of spas, appointing in each case two medical men, one of them a practising spa physician, with the secretary, to visit the spa, make a thorough inspection of it, and report to the committee, the federation, and the spa itself. He also spoke of the need for more careful consideration of the holidays of the people—the "staggered holiday" education for holidays, organization to ensure the maximum benefit, to reduce overcrowding in health resorts, to encourage holiday camps, altogether to make the taking of holidays a rational thing instead of the random affair it often was.

Spas and the Public Health

Alderman BARROW of Bath, president of the British Spas Federation, spoke of the benefit of the conference which the British Health Resorts Association arranged at Bath a year ago. Sir STANLEY WOODWARD said that if only the B.H.R.A. embraced all the spas and health resorts of the country it would represent one of the finest movements for the health of the nation. Mr. W. McADAM ECCLES spoke of the benefit of rest at spas and health resorts, not only in convalescence but also before a severe operation, to enable the patient better to withstand the ordeal. Dr. G. D. KERSELEY, in congratulating Dr. Holmes upon his appointment at Leeds, mentioned that the Committee for the Study of Medical Hydrology, which had been helped financially by the British Spas Federation, had arranged eighteen lectures to medical men during the past year, and had arrangements in hand for others.

The annual report and financial statement—the latter illustrating the slender means on which considerable work can be done—were adopted, Lord Meston was re-elected president, and Sir Walter Langdon-Brown, Lady Honywood, Lord Horder, Sir Archibald Weigall, and Sir Stanley Woodward vice-presidents, and the meeting ended with the usual votes of thanks.

Reports of Societies

ENDOCRINE THERAPY IN GYNAECOLOGICAL CONDITIONS

At a meeting of the Medical Society of London on November 14, with Dr. C. E. LAKIN in the chair, a discussion was held on endocrine therapy in gynaecological conditions.

Mr. DOUGLAS H. MACLEOD said that endocrine therapy, apart from a few conditions in which it was specific, was still in its experimental phase, and it was important to remember this fact, both from the patient's point of view and from that of the reputation of the therapy. Except in endocrine clinics, which must be experimental, little discrimination was exercised in the use of the treatment. Oestrogen was of value in the treatment of severe menopausal symptoms, and the corpus luteum hormone was of use in cases of threatened or recurrent abortion for which no physical cause could be assigned. On the subject of biological assays of the hormones in the urine he said that before deciding on treatment by hormones in a case in which the symptoms pointed to functional deficiency it was logical to determine which particular hormone was at fault. The difficulties were manifold. The hormonal activity of the urine was an uncertain indication of the hormonal activities of the body. On the possibility of undesirable effects following hormone therapy, especially in view of the close relation between certain carcinogenic and oestrogenic substances, it seemed that the risk of the possible development of malignant disease was negligible, though it must be confessed that little was known on the subject. As for successful results, until biological assays of hormone activity were established it must remain impossible to tell in many cases how large was the part which the psychological element had played.

Hormone Assays

Dr. P. M. F. BISHOP said that it was necessary to realize that the endocrinologist in the laboratory was at present quite incapable of assisting in the diagnosis of any endocrine disorder by means of hormone assays. As a result of two years' intensive work by biochemists the androgens were now capable of fairly exact biological assay, but the oestrogens were a more difficult problem because of the series of degradation products. With regard to the gonadotropic hormone, it was fair to say that, apart from being able to give an 85 per cent. accurate result in a pregnancy test and helping to distinguish between a normal pregnancy and a hydatid mole, little could be done with the assay.

In discussing endocrine therapy it must be remembered that the response of a tissue to a stimulus depended on the strength of the stimulus and on the threshold of the sensitive tissue. There were tissues insensitive to oestrogen and tissues with different thresholds which required different concentrations of oestrogen to produce typical effects. Normal tissues were relatively insensitive to exogenous administration of hormones, presumably because they were already sufficiently saturated with the substance. Gonadotropic hormones were probably protein substances, but no idea was yet forthcoming as to their chemical constitution, and although extracted in fair purity from urine, there was no doubt that they did contain mixtures of other pituitary hormones. A still more difficult subject was the question of true pituitary extracts—extracts made from the pituitary lobe of different animals. The potency of pituitaries of different species varied within very wide limits.

Turning to clinical conditions, Dr. Bishop said that primary amenorrhoea as such, he thought, had never been affected by hormone therapy. In about 10 per cent. of cases of secondary amenorrhoea there was a permanent

re-establishment of the periods which could be directly attributed to the therapy, but the proportion, of course, was insufficient to rule out the possibility of coincidence. Apparently psychotherapy was just as effective as endocrine therapy in certain cases of amenorrhoea. Altogether endocrine therapy in amenorrhoea was so disappointing that he hesitated to advise it owing to the expense and inconvenience. He had gained the impression that large doses of oestrogen really did produce very good effects in a fair percentage of cases of true spasmodic dysmenorrhoea. The menorrhagias must be carefully classified before any attempt was made to evaluate the effects of endocrine treatment in these conditions. In selected cases a responsive group might be found. In a certain number of cases of sterility due to ineffective decidua, progesterone, given perhaps in the last week of the cycle, might be successful in assisting the implantation of the fertilized ovum. He believed that progesterone also had a place in the treatment of habitual and threatened abortion. Various reports of treatment of the toxemias of pregnancy had been published, but it was too early for conclusions on that subject. With regard to the menopause, his experience was that the administration of small doses of oestrin by mouth was extremely successful, provided the symptoms were not psychological in character. The results of treatment of secondary effects of the menopause were rather disappointing. Between such secondary effects of the menopause as psychosis, migraine, and so on, and ovarian deficiency, the relations were not sufficiently well marked to justify any optimistic expectations.

Limitations of Treatment

Mr. W. R. WINTERTON said that hormones were of the greatest value in conditions which were temporary rather than in those which were permanent. The factors which gave rise to secondary amenorrhoea were numerous and not necessarily of endocrine origin. Dysmenorrhoea might also be classified as primary and secondary, the secondary being a symptom of some other disease, and therefore not within the present discussion. Primary dysmenorrhoea was an ill-defined condition, and he had been told that one-third of the sufferers could be cured by any form of treatment—medicine, exercises, psychotherapy. Menorrhagia theoretically offered great scope for endocrine therapy, but the value of the treatment depended a good deal on the age of the patient. The treatment of sterility had been most unsatisfactory. Altogether endocrine therapy in gynaecological conditions must be said at present to have only a limited value. The wholesale use of hormones in unsuitable cases, necessitating as it did considerable expense for the patient, savoured of quackery. But in the symptoms resulting from the climacteric other treatments had been replaced by hormone treatment, and this was also true of threatened and habitual abortion and inhibition of lactation.

Dr. S. LEVY-SIMPSON said that there was evidently a very wide gap between the researches of the experimental endocrinologist and the "murky meanderings" of the gynaecologist and the gynaecologically minded endocrinologist. Endocrine therapy in gynaecology was rather an art than a science, and there was little doubt that one hundred years hence it would be regarded in much the same way as the magic potions of the Middle Ages. It must be extremely depressing to find that with all these advances in biological assay of the hormone content of urine and serum the matter was in such a hotchpotch of indecision that the clinician had once again to rely upon his hands and eyes and his sound clinical knowledge to guide him as to what endocrine product was the most likely to do least harm. The endocrine product which he had found of some use was testosterone propionate; it had cleared up a condition of dysmenorrhoea and menorrhagia in a young girl. Dr. A. P. CAWADIÁS said that an endeavour should be made to find the disease causing amenorrhoea or menorrhagia and to treat it by the various constitutional methods, among which endocrine therapy

must be included. Mr. V. B. GREEN-ARMYTAGE said that the treatment of secondary amenorrhoea by hormones was disappointing, but apparently many patients with this condition could be treated successfully by a fraction of an erythema dose of x rays.

Dr. BISHOP, in reply to this last point, said that low doses of x rays—which he believed to be very difficult to calculate—apparently stimulated the ovary. With regard to testosterone, he uttered a word of warning as to its possible effects in producing masculine characters in the female.

ASPECTS OF NEURITIS

At a meeting of the Manchester Medical Society on November 2, Dr. FERGUS R. FERGUSON opened a discussion on neuritis.

Dr. Ferguson, dealing particularly with multiple neuritis, said that it was quite impracticable to attempt a classification on any other than an aetiological basis, for, although the clinical and pathological pictures might be broadly similar, one found in detail that the clinical and pathological differences were not sufficiently marked to differentiate the various types of multiple neuritis. The most useful division was into exogenous and endogenous groups. In the former were the metallic and non-metallic causes. Almost all the metals except iron had given rise to polyneuritis, but he mentioned in particular lead, arsenic, mercury, and gold. With regard to the lead affection, it did not seem to be generally known that the lesion was in all probability not a true neuritis but a myopathy affecting the muscles which were principally used. Polyneuritis from arsenic and mercury was now relatively infrequent, but gold was a commoner cause of neuritis in view of its extended therapeutic use. Dr. Ferguson then referred to the many difficult and disputed problems connected with alcoholic neuritis—its mode of production whether due to alcohol, metabolic disturbance, or infection, and its relation to chronic gastritis, cirrhosis of the liver, and cardiac affections found in association with chronic alcoholism.

In the non-metallic exogenous subgroup there were the very interesting outbreaks of apiol and Jamaica ginger paralysis. The former was still important in that the product was on open sale and might be a possible cause of obscure cases of polyneuritis. Neuritis was a very common complication of diabetes, but it was rarely very extensive. It was not known whether the lesion principally affected the peripheral nerves or the cord. Diabetic polyneuritis was apparently never found in young people, and it seemed clear that there were numerous cases showing that the affection was one involving the cord rather than the peripheral nerves. Again, was the neuritis due to the hyperglycaemia, arteriosclerosis, sepsis, or diminished resistance? The differential diagnosis between polyneuritis due to diphtheria and that due to serum administration was important. In diphtheria the neuritis did not appear until about two months after the initial symptoms, whereas the serum polyneuritis showed itself very much earlier—within a few days of the serum sickness.

Acute Toxic Polyneuritis

Acute toxic polyneuritis was now the commonest cause of generalized polyneuritis. The clinical picture varied considerably as regards the severity of the initial symptoms, the relative affection of the motor and sensory pathways, the degree and distribution of the flaccid paralysis, the abnormalities in the cerebrospinal fluid, the course of the disease, and the prognosis. It was not widely known that cranial nerve paralyses were common findings in this condition. He referred to a patient with polyneuritis who presented herself with a Bell's palsy; a week later facial paralysis appeared on the opposite side. Careful investigation of the history revealed that paraesthesia had

been noted in the hands before the facial palsy developed, and later the patient had a generalized weakness in the limbs.

Dr. Ferguson said that no discussion on neuritis at the present time would be complete without reference to vitamin B₁ therapy. Despite the enthusiasm with which this form of treatment was introduced and the excellent results recorded in the early days, further experience was undoubtedly disappointing. It seemed almost certain that the only patients who would be benefited were those showing a diminished vitamin B₁ content in the blood, such as was found in beriberi and in the nutritional, gestational, and alcoholic groups. There appeared to be no definite improvement in acute toxic polyn neuritis, diabetic neuritis, and subacute combined degeneration of the cord.

Generalized polyneuritis was undoubtedly common at present, and although it was customary in the absence of any definite aetiological cause to make a diagnosis of acute toxic polyneuritis, yet one had to remember that the clinical picture of this condition varied considerably and that there was as yet no positive diagnostic test.

Orthopaedic Point of View

Mr. HARRY PLATT referred to the large number of affections of the spine and extremities which were unreasonably termed "neuritis." These included lesions of fibromuscular structures in relation to the larger joints, true joint lesions, and a variety of lesions of bone. There were two regions of particular interest to the orthopaedic surgeon—the shoulder and the lower spine and pelvis. In the shoulder region true brachial neuritis could be distinguished by definite signs of disturbance of conduction in the nerve trunks. A somewhat similar clinical picture was presented by toxic or infective peri arthritis of the shoulder-joint, a condition not uncommonly seen in middle-aged females. Following an attack lasting three to six weeks, characterized by pain in the neck, shoulder, and arm, the shoulder-joint was found to be stiff. The limitation of movement was due to the formation of fibrotic adhesions of the capsule and periarticular muscles. This was a condition most amenable to cautious manipulation under anaesthesia.

The "pseudo-neuritis picture" in the lower spine and pelvis was characterized by backache with unilateral sciatica. A special manifestation often seen in the acute stage was sciatic scoliosis. The problem of diagnosis in cases of sciatica was often most difficult and was of primary importance. Symptomatic treatment should never be prescribed except as a temporary emergency measure until an accurate diagnosis could be made. It was essential to approach the problem in a systematic fashion. The first step was to eliminate the possibility of pelvic visceral lesions; the next step to eliminate bony lesions of the spine and pelvis. This left three main groups of sciatica for consideration: (1) fibromuscular lesions (fibromyositis) of the lumbar region, buttocks, and hamstrings; (2) joint lesions affecting the lumbar spine, sacro-iliac, or hip-joint; and (3) intraspinal lesions, more especially tumours of the cauda equina and the recently discovered condition of protrusion of an intervertebral disk. The main features of these groups were discussed, and a brief reference made to the appropriate treatment of each type.

Physiotherapy of Neuritis

Dr. JOHN COWAN said that there was a great deal of uncertainty among medical men as to the most suitable form of physiotherapy to be applied in neuritis. Many unsuccessful results were due to a lack of proper understanding of the various measures, so that the choice of treatment and dosage was left to a masseuse. Often the masseuse applied treatment ineffectively owing to the absence of detailed instructions from the practitioner. In prescribing physiotherapy it was essential to have a good knowledge of the physiological and physical effects

of the various agencies. The conditions usually requiring treatment were pain, tenderness, loss of function, and loss of sensation. Pain was often referred to some distant area, and it was obvious that treatment in these cases would be ineffective if directed to where the pain was felt rather than to the site of the trouble. It was in these cases that masseuses so often treated the wrong area.

The site of a localized inflammation of the nerve could be discovered by applying labile faradism along the course of the nerve. On passing the electrode over the affected area the patient complained of acute pain. The chief therapeutic agent in the treatment of pain was heat. One had first to decide whether superficial or deep heat was required. Heat had an analgesic effect on structures in which it was absorbed. For superficial heating infra-red rays of the external band were the most suitable, as they were entirely absorbed by the skin and superficial fascia; they gave a marked skin reaction, and had also an analgesic effect. Ultra-violet rays caused a superficial reaction which lasted for a considerable time. For heating to the depth of a few centimetres infra-red rays of the internal band and numerous heat rays were most effective, as they were not absorbed until they had penetrated to that depth.

When deep heating was desired long-wave diathermy or ultra-short-wave diathermy was indicated. The choice between the two depended on the ohmic resistance of the tissues through which the current had to pass. Long waves tended to pass by ohmic resistance, and ultra-short waves passed by displacement or eddy currents. Consequently the former heated best tissues of low resistance, and the latter heated those which were screened by highly resistant tissue, such as fat. Another treatment applied for pain was anodal stable galvanism, which was effective owing to the area of anelectrotonus or decreased sensitivity around the anode. Chlorine, iodine, or histamine ionization would sometimes relieve pain because of its marked vasodilator effect, which acted as a form of counter-irritation.

Only the lightest massage (effleurage), and not pétrissage or tapotement, should be applied in the acute stages of neuritis, as the latter were too stimulating. A surface effect was desired for its sedative action on the sensory nerve endings. A valuable but little-known treatment for tenderness was by a fine high-frequency effleuve. This required an experienced operator, as a coarse effleuve was stimulating and would make the patient worse.

Loss of function was associated with disuse atrophy of muscles and joints. The wasting of muscles could be avoided, except in the severest cases, by applying surged galvanic currents or, better still, slow sinusoidal currents with a periodicity of about 2; these should be applied throughout the illness. As a rule surged faradism could not be tolerated. Because the patient adopted the position of ease for long periods, severe stiffness and contractures were likely to develop; they could often be prevented by massage—pétrissage and movements—especially if diathermy was applied first. Free active movements should be encouraged. Loss of sensation required stimulation of the sensory nerve endings. This could be done by applying high-voltage induction shocks by means of a wire-brush electrode; another method was to give a coarse high-frequency effleuve.

ENERGY AND MUSCULAR WORK

The twenty-third Guthrie Lecture of the Physical Society was delivered by Professor A. V. HILL, Sc.D., F.R.S., on November 11, at the Imperial College of Science and Technology. His subject was the transformations of energy and the mechanical work of muscles.

He said that the heat given out by muscles in relation to the work done by them was one of the classical studies of physiology. Till recently, however, the matter appeared

much more complicated than it really was owing to technical difficulties. These have been overcome by the use of a very rapid recording system and an insulated thermopile only 0.002 in. thick. Some very simple relationships had now emerged. An active muscle liberated energy in three forms: in maintaining a contraction, as heat; in shortening, as heat; in shortening against load, as work; its behaviour in any circumstances is deduced from the resultant of these three. Rate of total energy liberation of a muscle was determined by the load upon it, increasing as the load decreased. This allowed a simple equation to be deduced for the relation between speed and load. The constants of the equation were the same whether they were obtained by thermal or by mechanical measurements. This was strong confirmation of the results and of the conclusions based on them. Professor Hill showed how the time taken by a muscle in developing its external force could be deduced from these considerations and depended largely upon the amount of elastic material (tendons, etc.) in series with the contractile elements. The fact that a muscle did less external work when shortening at a higher speed had led to the hypothesis that muscle was endowed with "viscosity." This viscosity had been attributed to a lag in the rearrangement of its molecules, as the external form of the contractile elements changed. It was now shown that this viscosity hypothesis was altogether unnecessary and that the decrease of force and work with increased speed could be deduced from the manner in which the energy liberation was regulated.

Some applications were described by the lecturer. The maximum power developed by a muscle was with a load about three-tenths of the maximum load it could bear. The highest efficiency (work/total energy) was with a load of about 0.45 of the maximum. These were near enough for maximum power and maximum efficiency to occur very nearly at about 37 per cent. of the maximum load. These results obtained with frog's muscle almost certainly applied, though possibly with different constants, to man, and it would be very important to find out and to determine the constants of human muscle. The technique required would be a very different one.

LABORATORY DIAGNOSIS OF GLANDULAR FEVER

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, held on October 28, with the president, Dr. R. A. Q. O'MEARA, in the chair, Dr. D. M. MITCHELL gave a demonstration of the Paul-Bunnell agglutination reaction.

Dr. Mitchell said that infectious mononucleosis, or glandular fever, was a clinical syndrome characterized by fever, glandular and splenic enlargement, a benign course, and the presence in the blood of abnormal mononuclear cells in large numbers and, in the serum, heterophil antibodies to a high titre. Pfeiffer in 1889 was the first to describe a condition in children which he called *Drüsenfieber*, and which had a short febrile course accompanied by enlargement of the cervical lymph glands. It commonly occurred in house epidemics. During the next twenty years cases of glandular fever were often reported in the German and American literature, but in no paper was there any mention of the blood picture. Many authors, on the other hand, had described cases with a marked leucocytosis (as many as 90 per cent. of the cells being mononuclears, usually described as "lymphocytes") and accompanying illness, usually a fever of short duration, with enlargement of one or more groups of superficial lymph nodes. Several of these cases were reported as "acute leukaemia with recovery."

In 1920 Sprunt and Evans, at the Johns Hopkins Hospital, published an account of six such cases under the title of "infectious mononucleosis." In the following

year Tidy and Morley, in England, reported three more, and expressed the view that the infectious mononucleosis of Sprunt and Evans and the glandular fever of Pfeiffer and the early workers were the same disease. Even at the present time it seemed that in Europe the disease—if it was one and the same condition—occurred among young children in small epidemics and was generally known as glandular fever, whereas in the United States it most commonly appeared sporadically in young adults, and, appropriately enough, since the chief interest centred in the blood changes, was called infectious mononucleosis.

Paul-Bunnell Reaction

In 1932 Paul and Bunnell (*Amer. J. med. Sci.*, **183**, 90) reported from Yale the accidental observation that the inactivated serum of a patient suffering from infectious mononucleosis had the property of agglutinating sheep red corpuscles to a titre as high as 1:1024. They confirmed this finding in three other cases, the lowest titre obtained being 1:128. The only clinical condition in which such agglutination had previously been observed was in serum sickness after the injection of horse serum. The technique of Paul and Bunnell had been somewhat modified by Stuart to avoid certain difficulties in interpretation and to enable a standard method to be used by all workers:

1. The serum was inactivated in the usual way by heating to 55° C. for fifteen minutes.
2. Dilutions of serum in amounts of 0.5 c.cm. were put up in Wassermann tubes.
3. To each tube 0.5 c.cm. of a 1 per cent. suspension of washed sheep cells was added.
4. The tubes were then heated for four hours in a water-bath at 37° C. If necessary they might be left overnight in the ice-box and incubated the next day.
5. The tubes were inverted three times before reading and three degrees of agglutination were recognized:
 - + + + : cells agglutinated in a solid mat.
 - + + : cells agglutinated in large aggregates.
 - + : agglutination just visible, naked-eye.
6. Using this procedure a titre of 1:80 was considered suggestive, while one of 1:320 was diagnostic—with reasonable clinical and haematological supporting evidence.

The origin or nature of the antibodies remained obscure. Paul and Bunnell were of the opinion that they were of the same kind as those produced in serum sickness—that is, heterophil or Forsmann agglutinins, or, if the serum was not inactivated, haemolysins. This curious phenomenon of heterophil antigen-antibody reaction was first studied in detail by Forsmann in 1911. He observed that on injecting rabbits with an emulsion of guinea-pig organs there appeared in the rabbits' serum, as well as the ordinary specific antibodies, a completely distinct variety which had the property of agglutinating or haemolysing sheep cells. He found that the animal kingdom could be divided into two groups: those animals whose tissues contained the heterophil antigen, and those in which it occurred in the red cells only and not in any other tissue. In the first, or guinea-pig, group were found very many animals—including the horse. In the second, or rabbit, group were included man, the sheep and ox, and most pathogenic bacteria. Davidson later showed that persons who had received injections of horse-serum developed the antibodies in their serum, while those who had been injected with bovine serum did not; and, further, that in those who subsequently suffered from serum sickness the titre of antibodies in the serum was much higher.

Paul and Bunnell's view of the heterophil nature of the antibodies developing in infectious mononucleosis was supported by the work of Stuart. He showed that the agglutinins were quickly completely absorbed by raw sheep cells, more slowly but still completely by guinea-pig kidney (which contained the Forsmann antigen), and not

at all by rabbit cells. Furthermore, one patient who had a high sheep-cell agglutination titre reacted strongly to an intradermal injection of horse serum which contained the antigen—an observation which appeared to have a practical bearing on the treatment of infectious mononucleosis, suggesting that the injection of horse serum in these patients for any reason should be avoided. Other experiments which Stuart undertook produced results more difficult of interpretation. For example, serum containing heterophil antibody was toxic for the guinea-pig, and yet guinea-pigs into which Stuart injected serum from patients with a high sheep-cell titre developed only mild anaphylactic symptoms. One other observation was of interest. Landsteiner and others had shown that human red cells of groups A and AB contained the heterophil antigen. In Stuart's group of nine cases of infectious mononucleosis five belonged to group A, and one of these patients had a sheep-cell titre of 1:5120 for both agglutinins and haemolysins. Here, it would seem, were five individuals with the antigen in their red cells and the antibodies to high titre in their serum—a fact for which no obvious explanation was available.

General Discussion

Dr. R. A. Q. O'MEARA, the president, asked Dr. Mitchell if there was a possibility that these cells themselves—whether monocytes or lymphocytes—contained the heterophil antigen, and, their presence being abnormal, the other cells in the blood reacted by producing an antibody.

Professor J. W. BIGGER said that according to Dr. Mitchell most bacteria were supposed not to contain the antigen, but the antigen might occur in diphtheria bacilli. Some years ago he had immunized rabbits with diphtheria bacilli. He had examined the serum for sheep-cell haemolysins, which were found present to a high titre. The presence of the high haemolytic titre in the rabbits was probably due to their previous inoculation with diphtheria bacilli. This suggested that the diphtheria bacillus did contain this antigen. The question was, Had the serum of a person suffering from diphtheria the property of agglutinating these cells? It would be interesting to obtain some sera from diphtheria patients and test it with sheep cells, and also with concentrated horse-prepared anti-diphtheria serum, and see if it did or did not contain this antibody.

At the same meeting Dr. O'MEARA read a short communication on the optimal constitution of media for growth of the pathogenic micro-organisms. An interesting discussion followed in which Professors J. W. BIGGER and W. D. O'KELLY, with Drs. J. C. FLOOD, E. HARVEY, and J. McGRATH, took part.

At a meeting of the Association of Industrial Medical Officers held in the London School of Hygiene on October 28, Dr. L. P. Lockhart was elected chairman and Dr. D. Stewart honorary secretary for the session 1938-9. A discussion took place on "The Feet of the Industrial Worker," opened by Professor E. P. Cathcart, F.R.S., chairman of the Industrial Health Research Board. He was followed by Mr. C. Lambrinudi, who showed a film on the action of the muscles of the foot; Mr. W. Sayle Creer, who discussed the clinical aspects of the problem; Dr. W. Blood, who told of the foot clinic run by Messrs. J. Lyons and Co. at Cadby Hall; and Mr. H. Bradley, director of the Boot and Shoe Trades Research Association, who described recent research work carried out by his association on the provision of suitable footwear for industrial workers.

The Pasteur Institute of Algeria, under the direction of Dr. Edmond Sergent, has been authorized by Government decree to put on sale an anti-scorpion serum obtained from horses immunized by repeated injections of the venom of the brown African scorpion.

Local News

ENGLAND AND WALES

Royal Eye Hospital, London

At a meeting of the Clinical Society of the Royal Eye Hospital, St. George's Circus, S.E., on November 2, Mr. L. Vernon Cargill, chairman of the hospital, announced that the pathological laboratory and research department had been reconstituted. A new and highly efficient animal house had been made, and an investigation was being pursued into the retinal changes in rabbits. A technique had been developed in the laboratory for mounting macroscopic specimens without loss of colour; these specimens had been re-labelled and more appropriately catalogued according to the lesions demonstrated. Candidates for examinations could now review the whole field of ophthalmic pathology in a very short time. Attention was drawn to the excellent collections of melanomata of the choroid and intra-ocular foreign bodies, and the remarkable series of cases of expulsive haemorrhage. In the outpatient department there was a comprehensive collection of slides of all the commoner ophthalmic conditions; members of the hospital could now correlate very easily in their minds the ophthalmoscopic and microscopical appearances of the cases they met in the practice of the institution, and reference books were available in that department. Mr. R. H. Rushton demonstrated his new method for the clinical measurement of the axial length of the eye without surgical intervention. The principle of the method was that the retina when adapted to darkness was sensitive to x rays. A beam of x rays was moved forward until it impinged on the posterior pole of the eye when it was recognized entoptically by the patient; at the same time the position of the cornea was registered, and by a simple measurement the axial length was then determined. Important applications of this method in practical ophthalmology were the correlation of the axial length with the refraction in myopia. Mr. E. J. Somerset read a paper on the significance of errors of refraction in chronic blepharitis in children. His conclusions were based on the careful refraction under atropine of 300 cases. He had found that there was a similar incidence of refractive errors to that in normal samples of the population, and that there was no increase of spherical or astigmatic errors in blepharitis. Cases of monocular blepharitis did not show any greater incidence of blepharitis in the eye with the greater error of refraction, and causes other than errors of refraction must be sought for these cases. After the meeting members of the Clinical Society inspected the new animal house and its contents.

St. Ebba's Hospital, Epsom

The final extensions to the St. Ebba's Hospital for Nervous and Mental Disorders, Epsom, were formally opened by the Minister of Health, Dr. Walter Elliot, on November 16. St. Ebba's Hospital was first opened in 1903 as a colony for the care and industrial employment of epileptics, with accommodation for 326 patients. In 1909 the accommodation was increased to provide for 429 patients. From 1918 to 1927 the institution was used first as a hospital for soldiers and later for the treatment of neurasthenic ex-Service men. In 1927 it became once more an L.C.C. hospital for the accommodation of mental patients, and it was known as Ewell Mental Hospital; it was renamed St. Ebba's Hospital in 1937. When the Mental Treatment Act was passed in 1930 permitting for the first time the reception of voluntary patients in public

mental hospitals, plans were prepared for the enlargement of St. Ebba's. The extensions were carried out in two sections. The first, comprising an admission hospital villa, a hospital block for the physically sick, and a convalescent villa for male patients, as well as necessary enlargements of kitchen, laundry, and nurses' home, was finished in 1936 and has since been in use. The second section, now completed, comprises five more villas. The two extensions provide additional accommodation for 504 patients, bringing the total accommodation of the hospital to 933 beds—447 for men and 486 for women. In the administration of St. Ebba's Hospital as much personal freedom as possible is allowed the patients. Modern methods of treatment, psychological and physical, are followed, and the hospital is equipped with a clinical laboratory. At the opening ceremony Dr. Elliot said that they were that day celebrating the clearing away of a bad, an evil, tradition in the treatment of the mentally afflicted, in which the London County Council had made great advance. He spoke of the need for the feeling among doctors, staff, and the patients of the possibility of recovery of the patients. He welcomed the method adopted at that hospital of mixing the uncertified with the certified, and of treating the inmates as patients and not prisoners.

The Bart's Dinner

The dinner of the Old Students of the Medical College of St. Bartholomew's Hospital was held at the College Hall in Charterhouse Square on November 21, when Mr. Harold Wilson was in the chair. Owing to the death of the Queen of Norway, the Duke of Gloucester, who is President of the Hospital, was not able to attend. In proposing the "Welfare and Prosperity of the Medical College," Mr. Wilson gave a special word of welcome to the treasurer, Mr. George Aylwen. Bart's, he said, had fallen behind other hospitals in that it possessed no paying patients' block, and was therefore severely handicapped. Important events of the last year included the opening of the new athletic grounds at Chislehurst and the building of an attractive new pavilion. Sir Edward Meyerstein had most generously given the hospital an adjoining piece of ground. Referring to the achievements of old Bart's men during the past year, Mr. Wilson mentioned the knighthood conferred on Sir Girling Ball and the invaluable work he had done for the hospital and college. During the crisis the hospital had mobilized its forces and had ready operation services, a blood transfusion team, decontamination squads, etc. They realized that, whatever the circumstances, the hospital and school would somehow have to continue, and if war were to arise in the future the school would have to move out to some quieter and safer place, as the hospital would be a front-line dressing station. All these difficulties must be thought out and solved now. In submitting the civic toast, Mr. George Aylwen welcomed in the Lord Mayor of London, Sir Frank Bowater, a friend and governor of the hospital. The Lord Mayor, he said, had granted him the use of the Mansion House for a big appeal he intended to make on January 30. If his appeal was successful he was determined that one of his first efforts would be to build the paying patients' block. In a brief speech Sir Frank Bowater said that he always had the interests of Bart's at heart, a hospital whose doors had been open for over 800 years. In proposing "The Guests," Sir Girling Ball said this was the fifth year since Lord Horder had sat in the chair and launched an appeal to buy the buildings in Charterhouse Square. Of the £200,000 required, £184,000 had been received. Sir Girling said that one of his objects was to get the London hospitals to work together in their common interests, and to this end a Dean's committee had been instituted. Sir Robert Pickard, F.R.S., Vice-Chancellor of the University of London, replied for the guests, and Sir Charles Gordon-Watson proposed the health of the chairman.

SCOTLAND

The Health of Glasgow

Birth and death rates for the City of Glasgow have shown little change for some years, the birth rate in 1937 being 19.8 per 1,000 persons and the death rate 14.6 per 1,000. These figures are taken from the report for 1937 of Dr. A. S. M. Macgregor, medical officer of health for the city. An epidemic of influenza in the early months of 1937, states the report, caused 496 deaths, the highest figure for influenza since 1926. Whooping-cough was responsible for 285 deaths and diphtheria for 116 deaths. The death rate from pulmonary tuberculosis was 8.5 per 1,000 of the population, the lowest figure in any year with the exception of 1934; the general phthisis death rate has, however, varied little during the past ten years. The infant mortality rate was 104 per 1,000 births, being lower than the rate of 109 for the previous year, but the same as the average rate for the past ten years. The maternal mortality rate reached its lowest figure with 4.9 per 1,000 births, as against 5.9 for 1936; this fall was due especially to a smaller death rate from puerperal infections. General hospital accommodation is being gradually reorganized in Glasgow, and in five municipal hospitals the total accommodation is 4,165 beds, while the number of patients admitted to these hospitals has increased since 1931 by 33 per cent. The outdoor medical service for the sick poor has developed further as a whole-time service, most of the work being conducted by twenty-nine whole-time medical officers and eight part-time officers, with twenty nurses. The number of visits paid has increased from 23,230 in 1931 to 72,858 in 1937, while the number of consultations has risen in the same period from 113,217 to 302,560. The clinic system, wherever possible, is being amalgamated with other statutory services. There has been an increase in the number of patients admitted to the mental observation wards of the general hospitals, and the total number of patients under care in municipal mental hospitals during the year was 3,550. As regards mental deficiency, a gradual transfer of patients has been effected from the various general hospitals and other institutions to Lennox Castle institution, in which at the end of the year there were 988 defectives in residence.

Health Education

Dr. James M. Mackintosh, chief medical officer of the Department of Health for Scotland, addressing the Royal Philosophical Society of Glasgow on November 9 on the subject of health and the general practitioner, said the most intelligent and the most economical method of promoting positive health and of getting away from the notion that health was just the absence of disease was to regard all education as directed towards health. The family doctor had an immense contribution to make to individual and family health, but as we no longer expected the family doctor to undertake major surgery or bacteriology we should not expect him to undertake preventive medicine. When it was said that the doctor should be health adviser to the family, something quite different from preventive medicine in the accepted sense was meant. The family doctor should be trained to guide his patients towards healthy living, and it must be remembered that sickness of the mind rather than of the body was the greatest enemy of health in the family.

The French Minister of National Education has conferred the title of honorary professor on three distinguished members of the Paris medical faculty: Dr. Roussy, rector of the University of Paris; Dr. Brindeau, the obstetrician; and Dr. Sergent, the authority on pulmonary tuberculosis.

Correspondence

The Phosphatase Test and Pasteurization

SIR.—The description, in a leading article of your issue of November 19, of the calf-feeding experiments carried out at the National Institute for Research in Dairying at Reading and the Rowett Research Institute at Aberdeen calls for two comments.

First, what is the interpretation of the phosphatase test? In the original report it is stated that pasteurization at Aberdeen was effective because no trace of phosphatase was ever found in the milk. Yet a few pages later the report contains a table showing that 7 per cent. of forty-four samples of pasteurized milk were found by guinea-pig inoculation to contain tubercle bacilli. The authors plainly believe that a negative phosphatase test shows that the milk is safe. This is untrue. When it is remembered that this test cannot detect smaller quantities than 0.2 per cent. of raw milk in the pasteurized product, that tubercle bacilli may number tens or even hundreds in a cubic centimetre, that the deposit from 50 c.c.m. of centrifuged milk can be inoculated into a guinea-pig, and that ten living bacilli constitute an almost certainly infecting dose for this animal, it needs little calculation to realize that, unless the milk is only slightly infected, the guinea-pig inoculation test is more delicate than the phosphatase test. Like most other laboratory tests the phosphatase test is of far greater value when the result is positive than when it is negative. A positive result shows definitely that there is something wrong with the processing of the milk; a negative test does not exclude the presence of tubercle bacilli in the pasteurized product. It would be a pity if a test that is proving of such value in the control of pasteurization should fall into disrepute through failure to realize its limitations.

Secondly, why did the pasteurized milk used at the Rowett Institute contain tubercle bacilli at all? The observations of Pullinger (1934) in London on sixty-three samples of pasteurized milk, of the Public Health Authorities in 1936 in Manchester on 206 samples, and of Humphriss, Peden, and Wright (1937) in Liverpool on 440 samples failed to reveal tubercle bacilli in a single sample of pasteurized milk, even though the raw milk was frequently infected. It is abundantly clear that milk which is properly pasteurized is free from tubercle bacilli, and that so-called pasteurized milk containing tubercle bacilli has been unsatisfactorily treated, either on account of faulty design of the plant or through its imperfect operation. The fact that in the experiments at the Rowett Institute the pasteurized milk was found to contain tubercle bacilli will undoubtedly be used as an argument against pasteurization, whereas it is merely against the inadequate performance of pasteurization.—I am, etc.,

London School of Hygiene and
Tropical Medicine, Nov. 22.

Pasteurization of Milk

SIR.—When reading a paper on the essentials of nutrition in infants and toddlers at the Congress of the Royal Institute of Public Health and Hygiene last June, I stated that in my opinion all milk given as food should always be pasteurized, even if it were tuberculin-tested milk. In the ensuing discussion all the speakers agreed with this

statement with the exception of two medical officers of health from the North of England, who said that they had known milk that was labelled "pasteurized" to contain living tubercle bacilli. I replied that experience had shown that where milk had been "efficiently pasteurized" no tubercle bacilli were found, and quoted research demonstrating the fact. Milk being almost universally employed as a valuable food, I asked the chief bacteriologists of the two largest London dairies for the benefit of their experience on the above points, and append their replies.

Mr. E. B. Anderson, chief chemist to the United Dairies, said that the experiments by Professor F. C. Minett in 1933 on samples of their milk taken in ordinary routine revealed that of eleven samples of raw Grade A tuberculin-tested milk ten showed no tubercle bacilli, while in one sample tubercle bacilli were present. Of six samples of the same milk pasteurized none contained any tubercle bacilli. Then dealing with the "rail-tank" milk he found that each of forty-three samples of the raw milk contained tubercle bacilli, but forty-three samples of the same milk pasteurized were all free from tubercle bacilli. Such evidence surely speaks for itself.

Mr. Leslie Barton, principal bacteriologist to the Express Dairy Company, quoted somewhat similar evidence, and stated: "Since it has been positively established that tubercle bacilli cannot survive in milk properly pasteurized in accordance with the conditions laid down in the Milk (Special Designations) Orders, the conclusion can only be drawn that in the cases referred to the milk was improperly pasteurized." Both bacteriologists attach great importance to the phosphatase test.

Surely, from the precise nature of the information available, no open-minded man could doubt the reliability of efficiently pasteurized milk and the necessity for its universal use.—I am, etc.,

BERNARD MYERS.

Sulphonamide Chemotherapy in Surgical Infections

SIR.—Dr. F. R. Neubert, in a somewhat vague letter in the *Journal* of November 19 (p. 1053), is kind enough to refer to my articles on sulphonamide chemotherapy in surgical infections which appeared in your issues of October 22 and October 29. I make no comment on his unique success in curing gonorrhoea in the female with prosectasine, beyond noting his own statement that he has "employed the sulphonamide group extensively, but unfortunately without elaborate laboratory control." Those of us who have tried prosectasine in gonorrhoea with "elaborate laboratory control" have been less fortunate in our results. But I must point out that if Dr. Neubert had carefully read the articles to which he refers he would probably have refrained from stating that "Mr. A. J. Cokkinis emphasizes the need for waiting for immunity to develop before therapy is begun in gonococcal infections, does not advocate such a delay in streptococcal infections of the hand, and ignores the fact in other infections."

It is quite true that in streptococcal infections of the hand with lymphatic spread, in which the real danger is a fulminating septicaemia, I do not advocate waiting for immunity before chemotherapy is started. But this is the only exception. In every other infection I make some reference to the importance of raising immunity before starting chemotherapy. Thus, in the section on gingivitis I state that "the patient is given injections of vaccine for two or three weeks" before sulphonamide chemotherapy is started, and I repeat this in the section on streptococcal stomatitis and pharyngitis. My emphasis on waiting for immunity in gonococcal infections is conceded by Dr. Neubert. In the paragraphs on coliform urinary infections

I write that "it is now my practice to give an autogenous vaccine for one to four weeks before starting sulphonamide treatment"; while in the section on acute appendicitis I state that chemotherapy in the first forty-eight hours is unwise as it may interfere with the immunity response, but that in more advanced stages when the immunity response is awakened I have found sulphonamide compounds of real value as an adjunct to operation. A similar observation is made in the section on acute general peritonitis, where I also write that "the deciding factor [of chemotherapy] again appears to be the immunity response of the patient." Finally, I also advocate preliminary vaccine treatment in the chemotherapy of toxic arthritis, while the conclusion at the end of my article is nothing more than a statement which emphasizes the importance of immunity in chemotherapy.

After taking all this trouble to sing the praises of immunity and immunotherapy it is rather strange to be accused of "ignoring the fact."—I am, etc.,

London, W.1, Nov. 21.

A. J. COKKINIS.

Congenital Atresia of Oesophagus

SIR,—I was very interested in the excellent account of congenital atresia of the oesophagus by Dr. J. W. D. Bull which was published in your issue of November 12 (p. 983). Up to the present the sad story of these patients has always been the same, but I should be sorry to conclude that the problem of their treatment remains a forlorn hope. Although the author suggests that associated congenital lesions may often imperil life there were none likely to lead to a fatal issue in his case, and there are many on record in which such associated lesions have been absent. I can vividly remember when it was customary to regard patients suffering from ectopia vesicae in exactly the same way, and I have heard well-known authorities affirm that such children were better dead as there was no known means of relief.

But in the last thirty years or so all this has been changed, and as a result of developments in operations for the transplantation of the ureter many of these patients have been converted into useful and happy citizens. Even lesser deformities have sometimes been regarded as almost beyond hope of effective relief, and the same unhappy attitude has been adopted in the not very distant past in cases of cleft palate, imperforate anus, and urethral deformities. In all these conditions, as the result of the continued efforts of many workers, the outlook has become hopeful rather than forlorn, and in most cases great and effective help can be given by surgery. Admittedly the oesophagus problem is surrounded by great and especial difficulties, but it must not be allowed to remain unsolved for lack of endeavour.—I am, etc.,

British Postgraduate Medical School, G. GREY TURNER.
London, W.12, Nov. 21.

SIR,—The short article on this subject by Dr. J. W. D. Bull in the *Journal* of November 12 (p. 983) is a curious example of incomplete research. He says "the condition has been so seldom mentioned in the English literature." I know of no standard English textbook of children's diseases which fails to mention the condition, and many—for example, John Thomson's—give illustrations of it. Further, in 1917 Cautley in the *British Journal of Children's Diseases* (1917, 14) reviewed the cases to that date exhaustively, and the late Professor Shattock showed at the old Pathological Society in the early 1890's (I have not here got the exact reference) that the condition was found

also in animals, and gave a convincing explanation of its origin. Lastly, the condition is illustrated by many specimens in London pathological museums.—I am, etc.,

Ormond Street.
Basingstoke, Nov. 16.

Estimation of Blood Vitamin B₁

SIR,—We are very interested in Dr. H. M. Sinclair's criticism of our results on blood vitamin B₁ (*Journal*, November 19, p. 1060).

In the first place we should make it clear that our paper was written primarily from the clinical point of view, and therefore in order to keep it to a reasonable length we omitted unessential details and reserved them for a further discussion elsewhere. Many of the difficulties associated with the test were considered by Meiklejohn (working in Professor Peters's laboratory) when he first described its application to blood in 1937 (*Biochem. J.* 31, 1441). The practical details and much of the evidence in favour of the test, which we have summarized, can be found in Meiklejohn's paper, which in part deals with some of Dr. Sinclair's criticism, although, like Dr. Sinclair, we do not entirely agree with all Meiklejohn's results. We are pleased to hear that Dr. Sinclair has been able to improve the method and look forward to the early publication of his details. We are, of course, very familiar with the criticisms of Williams, van Veen, and others, but we are not prepared to admit their entire validity. Dr. Sinclair refers to the effect of a "pinch of chalk"; we investigated the effects of calcium carbonate in definite amounts of 0.5 to 5 milligrammes, but failed to find any significant alterations. It may be that other substances influence the growth of the mould, but this can hardly be said to invalidate the value of the test when carried out under standard conditions any more than, say, the exceptional presence of reducing substances interfering with the estimation of a blood-sugar or a glucose-tolerance test, or the presence of phenolic substances in the urine giving colour reactions with ferric chloride, invalidate these tests as useful procedures.

Nevertheless, in spite of the various objections, we still maintain that Meiklejohn's test, if done under standard conditions, is of great value as a comparative test for blood vitamin B₁ and is more accurate than any other method as yet described, so far as we know; this is surely confirmed by the fact that Dr. Sinclair has arrived at similar results independently. We have no experience of Harris's bradycardia technique, which has been of special value in the urinary estimation of vitamin B₁ deficiency (*Lancet*, 1938, 1, 539).

The experimental work on which our paper was based was completed in February by one of us (E. N. R.) for a dissertation; since then we, like Dr. Sinclair, have also added considerably to the number of controls and patients investigated, with results strictly comparable to those described in our paper.

We are quite aware that the few cases and controls we have reported in the paper are "statistically worthless," and that is why we did not treat them statistically. All our cases and controls were seen, examined, and diagnosed by us, and have been selected from the wards of the Manchester Royal Infirmary and from the 9,917 attendances of patients in our departmental clinic during the period of this investigation, so that the relatively small number of suitable cases led us to believe that we could hardly expect to get a sufficient number of cases of vitamin B₁ deficiency to justify a statistical survey. We are sure

these numbers do not exist in this part of the country, although perhaps Dr. Sinclair may be more fortunate in Oxford.

Finally, we would emphasize once again that the only patients showing clinical improvement on vitamin-B₁ therapy were those with apparent low blood vitamin-B₁ values, and reference to the concluding paragraph of our conclusions in the article in the *Journal* of October 29 (p. 878) will show that we described gross deficiency between 3.5–4.8 µg. and the one of 5.5 µg. We shall be pleased to hear in due course the value that Dr. Sinclair considers indicates a gross deficiency, and also his range of normal values, since he only gives in his letter the mean (11.5 µg. per 100 ml.), which conveys little to us.—We are, etc.,

E. N. ROWLANDS.

JOHN F. WILKINSON.

Manchester, Nov. 16.

SIR,—I thank Drs. Rowlands and Wilkinson for their answer to my letter published in the *Journal* of November 19 (p. 1060), and I am glad that they intend to discuss the method further in another publication. They state that the possibility of other substances influencing the growth of the fungus "can hardly be said to invalidate the value of the test," and draw an analogy with the exceptional presence of reducing substances not interfering with a blood sugar test: such an analogy is false because, as my letter showed, blood *invariably* contains substances (other than vitamin B₁) that affect the growth of the fungus under the conditions of the test. I have, however, never doubted the value of the method as a comparative test of the apparent vitamin B₁ in blood, as can be judged by reading the four publications in which I have mentioned results obtained with it.

I am glad that the authors agree with me that their cases and controls are statistically worthless. But Drs. Rowlands and Wilkinson try to justify their failure to treat the results statistically on the plea that there is a relatively small number of suitable cases in their part of the country. I showed in my letter that none of their cases was deficient when judged by an analysis of the eight normal controls upon whom they based their normal range: surely there cannot be a deficiency of suitable normal subjects in Manchester. And I still do not understand why in one part of their paper they regard 5.5 µg. per 100 ml. as "gross deficiency" when a figure below this value is elsewhere regarded as a "normal level."

In the last paragraph of their letter they wish to know my "range of normal values, since he only gives in his letter the mean (11.5 µg. per 100 ml.), which conveys little to us." Reference to my letter will show that determinations on twenty-six normal controls "gave a mean of 11.5 µg. per 100 ml., and a statistical analysis showed that there is one chance in 100 of an observation falling below 7.7 or above 15.2." It is sad that this statement conveyed little to the authors. In a paper published with Dr. Laurent (*Lancet*, 1938, 1, 1045) we stated that "a value below 7 µg. per 100 ml. is regarded as being abnormal."—I am, etc.,

Oxford, Nov. 18.

H. M. SINCLAIR.

Vitamin B₁ and Insulin

SIR,—I have a diabetic patient, a man of 56 in affluent circumstances, who takes on an average 32 units of insulin a day—20 units in the morning before breakfast and 12 before dinner. He eats what he likes, and his urine is kept free from sugar unless he goes to a dinner, and ball, etc. He is otherwise a comparatively healthy man, somewhat neurotic and apprehensive about his health.

After his return from a fishing holiday in early September of this year I put him on a course of six intramuscular injections of betaxan (a Bayer preparation of synthetic vitamin B₁), giving him one injection daily of 1 c.cm. These injections had a very good tonic effect, and some slight neuritis he was complaining of in his right arm disappeared. A fortnight ago he went to Bournemouth for a change. During the latter part of this holiday he was not feeling as fit as he thought he should, and he himself repeated another half-dozen intramuscular injections of betaxan. He returned to Bath on Saturday, November 12, and the following Thursday night he showed marked symptoms of hypoglycaemia in that he hardly understood how to undress and felt, as he described it himself, as he would imagine one to be when dead drunk. His wife was greatly perturbed, as he lost all colour and was perspiring profusely. She administered barley sugar, and he was all right again the following morning when I saw him at 9.30 a.m.

He told me, however, that he had noticed while taking the betaxan that he required much less insulin; in fact, on dropping his evening dose there was no sign of sugar either at bedtime or in the morning, and he felt extraordinarily well.—I am, etc.,

Bath, Nov. 19.

A. GORDON WATSON.

Treatment of G.P.I.

SIR,—I am unable to agree with Dr. W. D. Nicol (*Journal*, November 12, p. 1012) that electrotherapy has been too recently introduced to arrive at comparative conclusions as to its results in the treatment of G.P.I. Ample time has elapsed. Apart from the question of mortality, about which there can be little doubt, the claim of electrotherapy to adoption, if only on the grounds of the illness and uncertainty associated with malarial infection, cannot be overlooked.—I am, etc.,

St. Mawes, Cornwall, Nov. 14.

B. H. SHAW.

Decline of Breast-feeding

SIR,—The correspondence on breast-feeding is of much interest and in some ways corroborates experiences in the past eighteen years. Since 1920, both from ante- and post-natal municipal clinics and in a large special department of a maternity hospital (out-patient department and fifty hostel beds for mothers with babies), we have had 90 to 95 per cent. successful breast-feeding, even where, in an overlapping district, health visitors not attached to our hospital have said: "Breast-feeding is practically impossible." To achieve this, nothing has been done which is not within the power of the average working-class mother; but the attitude of all concerned has been that breast-feeding is natural, best for mother and baby, usually easily come by because natural, and only wanting a little common-sense management or adjustment, without worry or impatience, to secure smooth working where that is not immediately obtained.

Because we know that poor women cannot spend sixpence a day on milk for themselves during pregnancy and lactation, and more likely than not will give instead to the family any milk that is provided free, we serve out to them the ordinary but fresh calcium lactate, which costs sixpence a fortnight, and thus (apparently successfully since 1920) help to guard against the calcium deficiency of a minimum diet.

The patients (being under V.D. treatment) are carefully instructed on non-stimulating diet and at the same time are told how to obtain the most necessary items at low cost—for example, cheap plain cheese, wholemeal bread, coarse cereals, uncooked fruit, and vegetables, fresh herrings and sprats when in season, nuts,

etc., with abundant water between meals. During pregnancy meat is limited, but liver two or three times a week is allowed. During lactation a meat-vegetable-pudding daily dinner is a desideratum.

The method of breast-feeding is very important, and we are constantly having to combat the pernicious "ten minutes each side" theory and to explain the necessity for "stripping" a cow to get full milking next time and the advantages of the additional rest obtained by lying down to give feeds.

From personal experience I suggest that even in London there are clinics (as well as general practitioners) which are not as expert as they should be in the matter of breast-feeding and too ready to give artificial foods.

Another factor of importance is the influence of the nurse in charge of maternity cases.—I am, etc.,

London W1 Nov. 8

D. C. LOGAN.

SIR.—Having read with great interest Dr. J. C. Spence's able article on breast-feeding, and also the ensuing correspondence, I felt that the remarks made by "Juvenis" (*Journal*, November 5, p. 967) could not go unchallenged, for even if, as he says, the modern nurse takes full command of her patient's baby, it is surely a sign that there is something wrong with the system which puts a nurse into this position and which trains her for this end. The second point raised by "Juvenis" is in my opinion one of the chief causes of the present failure to breast-feed in so many cases, and the increased hospitalization of normal midwifery cases has surely played some part in introducing this "environmental factor." The mother in her own home is the mistress of the household, the pivot on which the family life revolves, and in this sphere she is a confident woman, sure of her own powers. In the early stage of her labour she can to a certain extent go about her usual duties, and when the time comes for her to be delivered she is in familiar surroundings and has not to face the ordeal of meeting strangers at the critical moment. Her medical attendant as her family doctor is a person in whom she has confidence, and should an obstetrician be required she has her doctor's assurance that he is obtaining the very best help. She will also have had an opportunity of getting to know her midwife during ante-natal days. After the confinement is over and the doctor and nurse depart, the mother can fall quietly into the reactionary sleep which is her natural preparation for the task of feeding her child, and she can put her baby to the breast whenever it cries during the first few days, and in doing this she becomes conscious of her own power to satisfy its needs.

When we compare this normal state of affairs with a confinement in hospital we can see a very marked and vital difference. The patient entering a hospital is a stranger in a world where doctors and nurses rule, and she is no longer a person who can control her own activities. In the first few hours she may pass through the hands of several nurses, in the admission room, waiting room, and labour ward, and if it is her first experience of hospital life she is bewildered by the sight of trolleys and shining glass shelves containing mysterious bottles, not to mention the hospitals where it is the custom to keep an instrument cupboard in the labour ward. The length of time for which the mother is left to rest in the labour ward varies according to whether it is likely to be required for another case, so shortly after delivery she is put into the general ward, and, as "Juvenis" says, she has to be given bedpans, meals, etc., at stated intervals and must feed her baby by the clock. This routine is

absolutely essential if the smooth running of a hospital is to be achieved, but very few of us would agree that it is ideal.

A point which has been brought very much to my mind during the reading of the recent letters is that one finds in practice that where there has been extensive preparation of the breasts during pregnancy breast-feeding is not too successful; there does seem a possibility that this stimulation of the breasts prematurely creates some psychological hostility to breast-feeding. One feels that it may be wiser to advise nothing more than a good standard of cleanliness, in order that no stimulation of the breasts may take place until the right time in the cycle of reproduction—that is, response to the child's sucking. Many women have told me that this preparation of the breasts by scrubbing and drawing out the nipples has made them feel very sick of the idea of breast-feeding.—I am, etc.,

Liverpool, Nov. 10 MARY CUNNANE, S.R.N., S.C.M.

Adrenaline Treatment of Asthma

SIR.—Dr. Joah Bates in his letter (*Journal*, October 29, p. 921) raises two questions about the adrenaline treatment of the acute asthmatic attack which are of importance. They require elucidation lest without good cause a seed of doubt should be sown as to the efficacy or even advisability of injecting adrenaline in a case of true allergic asthma. This line of treatment is a most potent weapon in our hands, and has stood the test of time in both theory and practice. His first point, which deals with the frequent onset of bronchitis in asthmatics who contract a common cold, can be accepted as a fact, for these sufferers are admittedly more susceptible to respiratory infections than perfectly healthy individuals. However, I know of no evidence suggesting that the administration of adrenaline increases this tendency, and most people agree that the sooner the spasm is relieved by physiological means (that is, adrenaline) the less likelihood will there be of establishing a "place of lowered resistance" in the lower respiratory tract. Such, indeed, has been my experience with asthmatics with coryza. One finds, of course, invariably that the patient coughs, sometimes very persistently, after the attack has subsided, this being due to the release of mucus which had been dammed up in the mucous glands of the bronchiolar wall.

The type of case which Dr. Bates next describes, where a patient has been given several injections of adrenaline at intervals of two or three hours and remains dyspnoeic and cyanotic, can probably be divided into two classes. A number of these are not cases of asthma but of the paroxysmal dyspnoea of left ventricular failure (formerly called cardiac asthma), in which active pulmonary congestion is certainly present but the cause of this lies in the failing heart. Other cases are probably those of true asthma which have gone into that most distressing condition status asthmaticus. For its treatment injections of adrenaline at intervals of two to three hours are often inadequate, but it will usually respond fairly quickly to Hurst's method of continuous injection of 1 or 2 minims every thirty to sixty seconds, leaving the needle *in situ*.—I am, etc.,

York, Nov. 13.

H. ROYLE.

SIR.—While agreeing with Dr. Alexander Francis (*Journal*, November 5, p. 966) as regards the effects of the topical application of adrenaline or ephedrine to the nasal mucous membrane, I feel that the latter part of his letter calls for some comment. Dr. Francis tells us that he "had one asthmatic patient who, as the result of

repeated operations for the removal of nasal polypi, had required over 60,000 injections of adrenaline." These astronomical figures caught my eye. Surely there is either an error here or else Dr. Francis is actually telling us that the patient received one injection daily for 164 years, or two daily for 82 years, or four daily for 41 years, etc.—a truly remarkable record of endurance on the part of the patient and/or faithful service on the part of his medical adviser. One is hardly surprised to read further on that "his skin became so tough and hypersensitive that he needed a specially sharpened hypodermic needle." The marvel is that he allowed any form of instrument to be brought near him at all. But as a practising rhinologist what I really must quarrel with is Dr. Francis's assertion that this intensive treatment with adrenaline was "the result of repeated operations for the removal of nasal polypi." Sweeping statements of this kind are misleading, and may be dangerous.

In the first place, as is well known, nasal polypi may be due to allergy, infection, or both; but recurrent nasal polypi indicate the presence of either malignant neoplastic changes or some underlying ethmoidal disease. Dr. Francis does not tell us how often the polypi had been "repeatedly" removed, but I can give it as my firm conviction that had the full aetiological significance of the recurrence of the polypi been appreciated, thorough investigations been made, and adequate appropriate treatment been given, then the patient's asthma would probably have been considerably benefited and he would at least have been spared from assuming the—I feel sure reluctant—role of a human pincushion.—I am, etc.,

Bath, Nov. 19.

C. A. HUTCHINSON.

Anti-pernicious Principle in Urine

SIR,—Following the paper on the anti-pernicious principle by Dr. Edouard Jéquier and Major G. R. M. Apsey, published in your issue of November 5 (p. 934), it may be of interest to record the preparation from normal urine of a concentrated fraction which would be expected to contain the anti-anaemic principle if it is present in urine in the same form as it occurs in mammalian liver.

A process (British patent 473064) which had been shown previously to give consistently active and very concentrated anti-anaemic fractions from liver was applied to normal urine. The fraction obtained was prepared for parenteral use so that 1 ml. of the final solution was derived from 1,750 ml. of normal urine. Professor L. S. P. Davidson kindly tested this preparation on a patient suffering from pernicious anaemia with an initial red blood cell count of 1.31 million; 16 ml. of the concentrated urine preparation (derived from 28 litres of normal urine) were given intramuscularly over twenty-three days, without any significant reticulocyte response. A preparation of known potency subsequently gave a satisfactory response.

Although an isolated test is in no way conclusive evidence of the absence of the anti-anaemic factor in normal urine, this result may be of interest to other workers in this field.—I am, etc.,

New Menstruation Toilet

SIR,—During the last few months I have often been asked by young women whether I considered this new practice of plugging the vagina with absorbent tampons instead of using sanitary pads advisable and healthy. My reply is that it is not at all a good thing to do, because

vaginal plugs become very offensive and infected even when introduced by the surgeon under the best aseptic technique, and when introduced by a woman herself, under ordinary daily conditions during menstruation, the dammed-up blood in the vagina forms a perfect culture medium, and a profuse growth of septic organisms results. This practice is likely to result in vaginitis, cervicitis, and *B. coli* infections, with quite a possibility of sterility following as well as the other well-known complications of the above conditions.

Is it realized how popular this practice is becoming? The "outfits" are procurable at many big stores, and are presented to girls by women who extol their harmlessness and many advantages. For health and beauty classes, dancers, factory girls, etc., they have great attractions, as they require no belt and are comfortable and unseen. The literature accompanying them is all that these young women have to guide them. Quite a lot of doctors seem to be recommending them, but I feel sure that they have forgotten what a vaginal plug is like after its removal; indeed, this is a job usually left to nurses. I shall shortly have a series of reports from bacteriologists on the growths obtained from the discharge before and after the use of these popular vaginal plugs, but in the meantime I think it is only fair to the female public to give some advice on the subject, or is it a matter for the Ministry of Health?—I am, etc.,

London, W.1, Nov. 11

E. LAWTON MOSS.

Evacuation of Air Raid Casualties

SIR,—Now that the crisis is over we have time to reflect on the inadequacy of the emergency plans made for dealing with air raid victims in our large cities, and we can prepare plans in advance for dealing with such a situation should it unfortunately occur again.

It is, I think, generally accepted that in a future war our large cities, and particularly London, would become virtually our "front line," and, as every ex-regimental medical officer knows, one of the most important jobs is to find means of evacuating the wounded to the back areas as soon as possible, where they can receive the attention which is not available in the front line. This was often difficult under shell fire in France, although there one was dealing with disciplined troops.

I suggest that in a great city containing a large untrained civil population, liable to panic when subjected to intensive high explosive and incendiary bombing, the difficulties would be infinitely greater, and especially if road transport were used for the conveyance of the wounded to the safety zones. The roads would probably be blocked by fallen masonry, fires, and the petrol-containing cars of refugees. Also the patients would have to be conveyed, not the three miles or so to the casualty clearing station as in the last war, but a distance of at least forty miles to the safety zone without medical attention, and open to further bombing the greater part of the way. A great strain would be placed on the railways in time of war in moving war munitions and food, and moreover the big termini would be obvious targets.

One therefore has to think of an alternative route which would not be subject to these objections or useful for other purposes, and one recalls the excellent use made of the French canal system in the last war for evacuating wounded in barges with a medical officer and orderlies in attendance. The advantages of such a method were obvious in France, and I suggest they are very much more so in London and our big provincial cities. There are between fifty and seventy steam launches on

the Thames, each capable of taking from 150 to 250 passengers from London to Oxford, besides many smaller launches and barges. They could be converted into hospital launches in forty-eight hours, and by that means alone approximately 10,000 wounded could be evacuated per day. Furthermore, the barges on the Grand Junction Canal, which connects the Thames at Brentford with all the big cities of the Midlands and most of those in the North, could be converted into hospital barges, thereby doubling the number of evacuations. The wounded from these large provincial cities could also be evacuated down this canal to rural districts in the Midlands.

The safest place in an air raid would, I suggest, be the middle of the Thames above Westminster. The Thames is not a target but a ranging mark to an enemy bomber. An incendiary bomb will not "set the Thames on fire," and high explosive, excluding a very lucky direct hit, would displace nothing but water. I would therefore like to offer for consideration the use of the Thames and our canals as a practical method of evacuating large numbers of wounded from our big cities to the safety zones in time of war.—I am, etc.,

H. GRAHAM HODGSON, C.V.O., F.R.C.P.

London, W.1, Nov. 16.

Air Raid Precautions

SIR,—It is small comfort to find one's pessimism concerning A.R.P. at the time of the recent crisis—based, be it said, on personal observation, some personal experiences, together with some unimpeachable information—was so fully justified. It is not, however, until one reads Colonel Nathan's remarks in Parliament (*Journal*, November 12, p. 1021) pertaining to London and Dr. W. M. Ash's account of difficulties in the country (p. 1016) that one realizes the full magnitude of the chaos then impending. The statement made at a meeting at the Ministry of Health and quoted by Colonel Nathan is indeed illuminating: "Gentlemen, this emergency hospital service has just been created. You must expect bombs to fall on London at any moment. Do the best you can." Yet we have been told for months past that the casualties would run into tens of thousands! The dead, according to Colonel Nathan's remarks, were to be given about the same amount of attention as the living, and to quote Colonel Nathan again, "the authorities [local] had no instructions and no information, and no intention, unless instructed, of dealing with the situation." And yet one bomb can easily kill an unlimited number of persons!

The above two illustrations, coming as they do from the ends of the administrative chain, show that the chain forged in times of peace snapped at the critical moment in the face of a war emergency. It is not surprising that this occurred, for who could possibly imagine that two Government Departments—the Home Office and the Ministry of Health—could administer, let alone co-ordinate, a scattered and mixed bag of authorities, organizations, and individuals constituting A.R.P. from headquarters in London? A trained and disciplined army requires a full staff from the War Office downwards, and if A.R.P. is going to be of any use whatsoever a modified but similar system of staff control is required, and required quickly, before many otherwise enthusiastic volunteers become tired of the muddle and procrastination. An adequate nucleus to these A.R.P. staffs, having full staff officer's status, could be formed from the county and borough officials, etc., providing, as they would, a permanent personnel constantly available for duty, thus maintaining a skeleton emergency staff.

Granted the foregoing, it should not be beyond possibility to split the country up into x A.R.P. command areas, similar to the military commands in this country, and subdivide these areas into x county areas, which would contain x districts, small towns being regarded as one district, large towns being regarded as two or more districts. London could be treated as a command area, subdivided into sub-areas, and again divided into districts. Thus an administrative chain would be formed from district to county area, thence to command area, thence to the directorate of A.R.P., London, whereas in London itself a similar procedure would be followed, though with a different nomenclature. In conclusion I would like to say that I cordially agree with Mr. J. Johnston Abraham's letter in the *Journal* of October 29 (p. 915).—I am, etc.,

W. V. FAWKNER-CORBETT,

Social Pathology

SIR,—I am encouraged by the amplification by Dr. J. L. Halliday (*Journal*, November 12, p. 1012) of my letter on this topic (October 8, p. 762). May I point out to him, however, that I spoke of the disintegration not merely of "this country" but of Western civilization as a whole. Like Oswald Spengler, I believe civilization to be of a piece. I suggested that for many years the social services had mainly been alleviating symptoms, and that, in carrying on these services, the best brains and energies of all countries had been progressively diverted from the task of safeguarding the health of the social organism proper—that is, of this whole Western civilization that I speak of. Dr. Halliday's way of putting it is to remind us that man is not in essence an animal but a living soul, a psyche, an individual; that to this essence his animal nature is subordinate; and that a civilization in which the public health and other services envisage only this "veterinary" aspect, while neglecting or even frustrating the psychological needs of its component individuals, is bound to perish. He sees, indeed, civilization ("this country," he calls it) destroying itself, as is evidenced notably by statistics of (a) a rising suicide rate; (b) a rising incidence of psychoneurotic and psychosomatic illnesses; and (c) a declining birth rate. To this he might perhaps add an increasing use of drugs; and in this connexion I am glad to see a letter from Mr. A. S. Playfair (November 5, p. 968) on science in advertising, which carries further the argument I had advanced in your correspondence columns of June 4 (p. 1235) under the heading "The Psychology of the Medical Profession."

Dr. Halliday has done well to include the falling birth rate as evidence of social dissolution. He seems, however, to have momentarily forgotten the most striking evidence of all—namely, the drift to world war. He will doubtless agree with me that the time is more than ripe for envisaging the disease of which all these are but symptoms or stages; piecemeal treatment has long since proved itself altogether ineffective. There are ominous signs of approaching collapse. What, then, is this disease that passes through the stages of declining birth rate and of mechanization and bureaucratization to world war, or, as we might more pithily put it, this movement from birth control to bombs? Can the essence of its pathology, and therefore of its treatment, be expressed in a formula? I think it can, but before venturing to bring such a formula forward I should much like to know whether any of my fellow practitioners are thus far in agreement with me; whether, indeed, they consider the speculation

likely to prove of any practical value at all. Surely life is not meaningless, and there must be laws of man's social as of his psychical and animal natures, and if so the medical perhaps above all professions is qualified to discover them. At least it has become abundantly clear of late that the politicians are quite incapable of doing so. They have no theory of society.—I am, etc.,

North Queensferry, Fife, Nov. 16.

A. J. BROCK.

SIR,—I have been much interested in Dr. James L. Halliday's letter in your issue of November 12 (p. 1012). I agree with him that the absence of action against environmental factors which frustrate the basic needs of a community will lead to the decline of individual and therefore of national health.

A certain quota of social interests is essential for the maintenance of full health. My work with people who are mentally ill has led me to see how far London fails in this respect. I have been struck, indeed, by the number of lonely people of both sexes, young and old. The growth of the urban at the expense of the country population is a contributory factor here. Rapidly growing large cities do not lend themselves as do long-established village communities to adequate social intercourse. This fact alone indicates the need for measures to combat this very real threat to social integration.

I suggest that one measure to meet this evil would be the opening up of a number of mixed clubs, adequately run on a non-political and non-denominational basis by a committee of capable people interested in social welfare. The aim of such a club would be the promotion of good fellowship and common interests. It might start quite simply in one room where members could meet, talk, play games, and so on, with perhaps the run of a kitchen or other apartment where light refreshments could be served.

I am quite certain that if a chain of such mixed clubs could be opened up throughout London and other large towns it would help to reduce that loneliness and lack of understanding and fellowship which really count as social evils. Driving people in on themselves, they favour the growth of neurosis in its many forms, leading in some cases to delinquency, drug-taking, and even suicide.—I am, etc.,

London, W.1, Nov. 19.

HILDA WEBER.

Prognosis of Anxiety States

SIR,—Let me assure Dr. Arthur Harris (*Journal*, November 19, p. 1063) that no knowledge of the unconscious mind was necessary to enable the criticism of his article on the prognosis of anxiety states to be made. It was a plain inference from the facts contained in the article, and, as Dr. Harris has again misunderstood it, I shall restate it in the simplest possible way, in the form of three propositions: (1) he set out to estimate the factors of prognostic importance in anxiety states; (2) he completely excluded the factor of treatment; (3) the obvious inference is that he does not consider treatment to be a factor of prognostic importance. Sir, surely Hamlet himself could 'hardly read' into this argument more than is affirmed.—I am, etc.,

London, W.1, Nov. 18.

FREDERICK DILLON.

A new law in Latvia ordains that every person suffering from venereal disease must be treated by a registered medical practitioner, who is entitled to search for the source of infection and make the suspected person undergo treatment also.

Universities and Colleges

UNIVERSITY OF OXFORD

At a Congregation held on November 19 the following medical degrees were conferred:

D.M.—T. M. Ling, *N. Chilton, W. D. W. Brooks, C. A. Boucher.

* By proxy.

UNIVERSITY OF CAMBRIDGE

At a Congregation held on November 19 the following medical degrees were conferred:

M.D.—*J. S. Cookson.

M.B., B.Chir.—*J. H. S. Hopkins, R. S. Morris, D. J. D. Torrens, J. H. Dixon, A. H. Baynes.

M.B.—R. C. Droop, R. L. Rhodes, L. A. Hawkins.

* By proxy.

UNIVERSITY COLLEGE, HULL

At a meeting of the Council, held on November 9, Dr. J. Morrison was appointed a part-time Lecturer in Education, and the British Medical Association Prize, valued £5, was awarded to D. R. F. Atkinson.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council, held on November 11, Mr. W. J. Lytle was appointed Honorary Lecturer in Surgical Pathology (Vice Mr. A. W. Fawcett); Dr. H. E. Harding Honorary Lecturer in Medical Pathology; and Mr. J. Hughes Honorary Demonstrator in Anatomy.

Professor H. N. Green, M.D., and Professor E. J. Wayne, M.B., F.R.C.P., were appointed two of the five representatives of the University on the Committee of Management of the Sheffield Hospitals Council.

UNIVERSITY OF GLASGOW

At a Congregation held on November 12 the following medical degrees were conferred:

M.D.—Marion Watson (with high commendation).

M.B., Ch.B.—W. H. R. Lumsden.

UNIVERSITY OF WALES

WELSH NATIONAL SCHOOL OF MEDICINE

The following candidates for the degrees of M.B., B.Ch. have satisfied the examiners in the subject indicated:

MEDICINE.—Alice Davies, Miriam E. Davies, G. C. D. Evans, W. L. Ll. Rees.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ANNUAL MEETING OF FELLOWS AND MEMBERS

The annual meeting of Fellows and Members of the Royal College of Surgeons was summoned for November 17, but after waiting for the prescribed time it was announced, for the second year in succession, that no quorum had been obtained, and therefore no resolutions could be moved.

Mr. Hugh Lett, the President, made a few remarks from the chair on the Annual Report. He said that during the past year primary examinations had been held in Melbourne, Sydney, Dunedin, Bombay, and Cairo; these had been quite satisfactory, and it was proposed this year again to hold examinations in India and Egypt. The College museum had attracted visitors from all over the world, and it had been enriched by a number of acquisitions. The library also had received a number of important gifts, among which he mentioned Sir D'Arcy Power's collection of transcripts of mediaeval MSS. of the works of John Arderne, the fourteenth century English surgeon. Professor Grey Turner had deposited on permanent loan his collection of autograph letters of John and William Hunter. The new Bernhard Baron research laboratories had been completed during the year, and the good work already done had aroused the interest of the surgical

world, not only in this country but over-seas. Grants had been made to research workers in the laboratories by the Medical Research Council, the Rockefeller Foundation, and the British Medical Association among other bodies.

Dr. Redmond Roche took up a remark in the report that the number of candidates admitted to the final examination during the year August 1, 1937, to July 31, 1938, was 1,372, an increase of 95 upon the figure for 1936-7, and of 195 upon that of 1935-6, and asked for comparative figures of the numbers admitted by the other licensing bodies.

The President replied that, taking surgery only, there had been increases of candidates for 1937 as compared with 1935 as follows:

| | |
|--|----------------|
| Conjoint Board | 1,235 to 1,290 |
| London University | 294 to 429 |
| Cambridge University | 224 to 243 |
| Society of Apothecaries | 117 to 141 |
| Durham University | 74 to 78 |
| Oxford University | 40 to 73 |
| Manchester University | 48 to 53 |
| Birmingham University (a decrease) | 50 to 46 |

Dr. Albert James Clarke, who had been chosen to move the usual resolution regarding the representation of Members on the Council, was unable to do so as the meeting was not properly constituted, but he was invited to make the speech he had prepared. He said that the present time would be a fitting one for the College to vindicate what was, after all, a principle of democracy—the right of representation of those who made a contribution to the commonwealth. Having regard to the changes which were taking place, not only in the social order but in matters affecting the profession, and also to the increasing number of candidates who were taking their medical degrees at the universities, he pleaded that the best interests of the College and of all whose welfare was bound up with it would be served if steps were taken to increase its corporate strength. This could be done, not by divorcing the Members from all participation in College affairs, but by according them some measure of representation.

Dr. P. B. Spurgin, president of the Society of Members, said that he felt that the Fellows entertained very friendly feelings towards the Members. They all belonged to a great College and were anxious to do all they could to promote its interests. What was wanted was greater co-operation, and a concession to the democratic principle of representation was the best way of bringing this about. Dr. Redmond Roche drew attention to some remarks made by Dr. Robert Hutchison, President of the Royal College of Physicians, at the opening of the new session at Westminster Hospital Medical School (*British Medical Journal*, October 8, p. 758), when he urged students not to be satisfied with a simple qualification to practise but to go on to a degree. That was a serious statement to come from such a quarter, apparently deprecating the value of the licence of the speaker's own College as well as that of the diploma of the Royal College of Surgeons. Dr. H. H. Sanguinetti also spoke in support of the request.

The President said that the various points made would be communicated to the Council at its next meeting. He appreciated what had been said about co-operation, and he sincerely regretted that the by-laws did not permit him to put the resolution to the meeting.

SOCIETY OF APOTHECARIES OF LONDON

Revision of Regulations for the Licence (L.M.S.S.A.Lond.)

New regulations and schedules, designed to meet the resolutions of the General Medical Council, in regard to professional education have been drawn up and may now be obtained from the registrar of the Society, Apothecaries' Hall, Water Lane, Queen Victoria Street, E.C.4. The new regulations and schedules take effect from October 1, 1939, and will be put into operation as follows:

Candidates presenting themselves for the pre-medical examination for the first time after October 1, 1939, will do so under the new regulations. Candidates who have sat for the examination before that date will be allowed to complete it under the old regulations, but thereafter will be governed by the new; after October 1, 1939, all candidates will take the primary examination under the syllabus of the new regulations; all candidates who pass the primary examination under the old regulations after October 1, 1938, will be required to take the finals under the new regulations.

The Services

DEATHS IN THE SERVICES

Major-General Sir JAMES MURRAY IRWIN, K.C.M.G., C.B., late R.A.M.C., died at Bideford on November 7, aged 80. He was born on February 13, 1858, the son of the Rev. James William Irwin, rector of Sharon, County Donegal, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., M.A.O. in 1881; nearly forty years later (in 1919) he received an honorary M.D. from his University. He was a prominent member of the Trinity College football fifteen. He passed into Netley in 1881, and joined the Army as surgeon on February 4, 1882. He became colonel on December 11, 1911, acted as major-general as Deputy Director of Medical Services in France during the war of 1914-18, and received an honorary step in rank as major-general when he retired on June 3, 1919. From 1906 to 1910 he held the post of Assistant Director-General at the War Office, and there, and subsequently as Assistant Director of Medical Services at Aldershot, took a prominent part in the reorganization of the Royal Army Medical Corps, which was effected under the late Sir Alfred Keogh as Director-General. He served in the Nile campaign under Kitchener in 1898, and received the medal and the Egyptian medal; and in the South African War from 1900 to 1902, when he took part in operations in the Orange Free State and in the Transvaal, including actions at Zand River, Johannesburg, Pretoria, Diamond Hill, Reit Vlei, and Belfast, was mentioned in dispatches, and received the Queen's medal with six clasps and the King's medal with two clasps. In the war of 1914-18 he served as Director of Medical Services of the Third Army under Lord Allenby; was mentioned in dispatches in the *London Gazette* of January 4, 1917, May 29, 1917, December 24, 1917, and December 30, 1918, and received the C.B. in 1917 and the K.C.M.G. in 1918; also the rank of Chevalier of the Legion of Honour. He joined the British Medical Association in 1882.

Major WALTER CROKER POOLE, R.A.M.C. (ret.), died in London on November 16, aged 75. He was born on February 27, 1863, in Northern India, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch. in 1885; he also took the Diploma in State Medicine in 1887. He entered the Army as surgeon on February 5, 1887, became major after twelve years' service, and retired on May 3, 1911. He served in the North-West Frontier of India campaign in 1897-8 with the Malakand Field Force, receiving the frontier medal with a clasp, and throughout the South African War of 1899-1902, when he took part in operations in the Orange Free State, the Transvaal, and Cape Colony, receiving the Queen's medal with three clasps and the King's medal with two clasps. He had been a member of the British Medical Association for forty-nine years.

Lieutenant JAMES WILSON GREENFIELD, R.A.M.C., died at Khartoum on September 20. He was educated at St. Andrews University, where he graduated M.B., Ch.B. only last year (1937). He entered the Royal Army Medical Corps on September 1, 1937, so had barely a year's service at the time of his death.

No. 29 GENERAL HOSPITAL DINNER

The twentieth annual reunion dinner of the 29th General Hospital will be held on December 3 at the Langham Hotel, Portland Place, W., when Lieutenant-Colonel S. H. Withers, C.M.G., will preside. Officers who wish to be present should communicate with the honorary secretary, Captain Percy Groves, Heronfield, Meadowcourt Road, Leicester.

Dr. W. A. Daley, a principal medical officer on the central administrative staff of the London County Council, has been appointed by the Council deputy medical officer of health to take charge of the public health department during any absence of the medical officer of health.

Obituary

SIR JAMES BARR, M.D., F.R.C.P.

Consulting Physician, Liverpool Royal Infirmary;
Past-President, British Medical Association

Sir James Barr died at his home, 16, Wilderost Manor, Putney Heath, on November 16 at the age of 89 years. He practised medicine in Liverpool for fifty years and retired from active work in 1926.

He was born at Cumber, Londonderry, on September 25, 1849, and was educated at Londonderry and at Glasgow University, where he obtained his qualification in 1873. His first appointment was as house-physician at the Royal Infirmary, Glasgow, and in the following year he was appointed house-physician at the David Lewis Northern Hospital, Liverpool. A few years later he succeeded Dr. Mitchell Banks (later Sir William Mitchell Banks) as medical officer to Kirkdale Gaol, a position in which his strong will and independence of mind manifested themselves in many ways. Through his intervention several reforms were carried out in the treatment and care of prisoners. In 1885, because of the prominence he had obtained for himself in this connexion and because of the urgency of the matter, he was ordered to Ireland by Mr. Balfour, the Secretary of State for Ireland, on the suggestion of Sir A. B. Walker, also a member of the Government, to report on the conditions prevailing in Irish prisons, which had been described as shameful by the Irish Members in the House of Commons, and in particular on the health of John Mandeville, who was then imprisoned in Tullamore Gaol for making seditious speeches. Shortly after Dr. Barr's arrival this prisoner died and the medical officer to the gaol committed suicide. Public opinion in Ireland at this time was impassioned by the activities of the Land League and the Irish Parliamentary Party, and these unfortunate events gave rise to intense indignation and political fury. Daring questions bearing baseless insinuations were asked in the House of Commons. Dr. Barr's life was threatened and he was offered police protection, but he only accepted it for his family. His expulsion from the Liverpool Medical Institution was demanded by its Irish members, but his membership was confirmed by an overwhelming majority, and the Irish minority withdrew never to return. Subsequently Dr. Barr was

presented with a testimonial signed by nearly two hundred members of the profession who resented the attacks that had been made on him while carrying out his duties. It was commonly supposed that his knighthood, bestowed by King Edward in 1905, Mr. Balfour being then Prime Minister, was a reward for these Irish prison services.

In 1887 he was appointed an honorary physician to the David Lewis Northern Hospital, Liverpool, and in 1897 an honorary physician to the Royal Infirmary, Liverpool. While holding these positions he helped to found the *Liverpool Medico-Chirurgical Journal*, of which he acted as editor for seventeen years. He became a prolific writer, papers on a great variety of medical subjects appearing in the various medical journals of the time: the earlier concerned cardiovascular diseases and mitral

stenosis in particular, the later nervous diseases, eugenics, and Abrams's box. His Ulster accent prevented him from being an attractive orator, but his writings were sincere and were faithful records of his observations in his wards, of his deductions from his reading and experience, interrupted by startling comments on matters that had little or no direct connexion with the subject. His paper on chiro-metaseosis in the *Medical Press and Circular* (October 4, 1922, p. 283) illustrates this feature of his later writings, but it also displays the leading characteristics of its author — his sturdiness, his virility, and his grim indifference to criticism.

Barr was elected President of the Liverpool Medical Institution in 1904, and his inaugural address on arteriosclerosis bristles with statements that cause surprise even to-day. An example may be quoted:

"In the case of a boy suffering from pericarditis after the removal of 20 ounces of serum, 40 minims of 1/1,000 solution of adrenaline the pulse disappeared at the wrist, and for a time the boy's life was in imminent danger. Here the cardiac failure was probably due to contraction of the coronary arteries, because the very small amount of adrenaline solution and its very rapid action preclude the idea of the failure being due to any general rise of blood pressure, or to inhibition."

He delivered the Address in Medicine at the 74th Annual Meeting of the British Medical Association at Toronto in 1906 on "The Circulation Viewed from the Periphery," and his address when he was elected President of the British Medical Association in 1912 was entitled, "What are we? What are we doing here? Whence do we come and whither do we go?" He delivered the Bradshaw Lecture before the Royal College

of Physicians of London in 1907 on "The Pleurae: Pleural Effusion and its Treatment." In these addresses it is obvious he made no pretence to literary style, preferring to drive his points home by vigorous thrusts and sledgehammer blows. Candour was his leading virtue. He revelled in giving expression to his thoughts and reasonings, such as they were. He could not maintain a discreet silence nor diplomatically turn an awkward question, yet throughout his writings it can certainly be said that there are no traces of malice or venom. His constant state of physical fitness was remarkable. He did not seem to know fatigue, and until an attack of influenza in 1918, when he was nearly 70 years, he had not experienced ill-health. His kindness was outstanding; he inspired confidence; he attracted men; yet for many years he was an outstanding leader of militant medicine and he remained a typical Ulster extremist.

He married the daughter of Mr. J. Woolley when he was aged 33 years and his domestic life was one of happiness. Their only son was killed in action in the great war. Their daughter Vera married Vice-Admiral Edward Astley Astley-Rushton, who was killed in a motoring accident in 1935. Lady Barr died in September of this year.

Professor Frank T. Paul, F.R.C.S., writes:

Sir James Barr came from Glasgow to settle in Liverpool some sixty years ago, shortly after I had been appointed resident medical officer at the Royal Infirmary. He was a keen, capable man, with the full intention of getting on in life, and was prepared to test all promising opportunities. We very soon came to know each other, and through all the rest of two long lives, though not following quite similar lines in work or holiday, we remained good friends throughout. There was not much left for either of us to do, but the break-up of such a friendship is a source of much regret.

Sir James began work as a general practitioner, but soon one of those many opportunities which he accepted occurred by the offer of a post just relinquished by the late Sir Mitchell Banks—namely, medical officer to Walton Prison. In this he soon showed his capability, which was recognized by the Government and taken advantage of by a request that he should inspect certain Irish prisons. His report proved to be valuable, and was, I believe, much appreciated. A more bright and happy change in his life soon followed, which I recall very well—his marriage with the charming and handsome lady who recently died. They had a son and a daughter. The former joined the Army and had the misfortune, when on a winter sports holiday with his father, to lose some of his toes by frostbite. However, he recovered without much permanent damage, and continued his life as an officer. He served in the great war and, with so many others, lost his life.

Sir James, after a few years of life in general practice, soon became immersed in the great changes which were taking place in the medical life of Liverpool. He gave much time and interest to the Medical Institution and was editor of the journal which reported its proceedings. He worked for many years in connexion with this Society, which has ever since been one of the most popular in the country. At the same time the Royal Infirmary was rebuilt on modern lines, and is a very successful institution. Sir James became a physician and we worked as corresponding colleagues for years together. In conjunction with Manchester, Liverpool shared the advantages of a university; but with the liberal help of our wealthy citizens we were able to establish the University of Liver-

pool. These times of great changes offered work for all, and so active a worker as Sir James Barr gave his share of valuable assistance in regenerating the old town to become one of the leading British cities.

After years of energetic life, and having succeeded in obtaining the honours Liverpool had to give him and the popular distinction of a knighthood, the time arrived when advancing age led him to decide on retirement. He left his Liverpool home—as usual in Rodney Street—and spent three years in hunting for the best spot in which to rest from work. He decided on Hindhead in Surrey, well worthy of his choice. When I had occasion to adopt the same line at the age of 80 he recommended his district, and we selected a home surrounded by woods and large commons at Grayshott. It was a great comfort to have such a good friend and capable physician near us. Only about a year ago, after we had been at Grayshott for about seven years, Sir James seemed to be in failing health, and Lady Barr was also far from being strong. Hence their daughter naturally felt that she would like to collect the remainder of her family to be near her in the neighbourhood of Putney, where she would be able to give them the intimate help they needed. Sir James was always a strong type of man; but strength has to yield to age in us all, and so those long years of friendship were broken, and the teaching of our mutual friend and much appreciated colleague, Sir Oliver Lodge, appeals with rather cold comfort to the surviving friend.

Dr. Alfred Cox writes:

Since his retirement from practice Sir James Barr has been little seen by his medical friends, and to the younger generation I suppose he is little more than a name. But his contemporaries will remember him as a forceful and combative personality. I suppose there never was a man who more loved a fight. I knew him first as a member of our Council in the early years of the century, but saw much more of him later in connexion with the historic Insurance Act fight. He was our President at the time the fight was at its hottest, and his contributions to the debate were never calculated to lower the temperature—quite the contrary. He was an individualist and an Ulster Tory to the core—whatever his nominal politics may have been. At Liverpool in 1912 he made remarks about the Insurance Bill and its author which received wide publicity. They certainly did not increase any reputation he may have had for moderation or judiciousness. His prophecies about the system read strangely to-day. One of his milder references to it was that it was "the most gigantic fraud that had been perpetrated on a confiding public since the days of the South Sea Bubble"! But Barr always called a spade at least a spade, and loved to rouse the spirit of combat. Away from his pet prejudices he was one of the kindest of men. As President he gave us a reception which yields for cordiality to none in my memory, and he was most ably seconded by his gracious wife. I remember vividly his presidential address, partly because of its extreme length, its many references to the Bergsonian theories, then much in vogue, and to eugenics, of which Barr was a warm supporter; its gibes at legislators and the occasional touches of his characteristic sardonic humour.

Those of us who knew Sir James in his prime will remember him not so much for the way in which we frequently and decidedly differed from him as for his zest in life and his invariable personal kindness.

PATRICK WATSON-WILLIAMS, M.D.

Consulting Surgeon, Ear, Nose, and Throat Department,
Bristol Royal Infirmary

Patrick Watson-Williams died at his home at Rodney Place, Clifton, Bristol, on November 14. By his death we have lost a most valuable and enterprising member of that small band of pioneers who in this country changed oto-rhino-laryngology from a casual occupation to a highly developed specialty.

Watson-Williams was educated at Clifton College and at the Bristol Medical School. He qualified with the diploma of M.R.C.S. in 1884, took the M.B. degree of London University in 1885, and the M.D. in 1890. In 1887 he was appointed house-

physician at the Bristol Royal Infirmary, and on the formation of the obstetrical department at that institution in the same year he was a candidate for the appointment, but withdrew his application before the election. The following year he was appointed assistant physician, which appointment he held for seventeen years before a vacancy occurred which enabled him to become a full physician. During this

period he took a particular interest in laryngology, and he was put in control of the nose and throat department which was formed in 1906; to this, four years later, was added the ear department, which had previously been under a general surgeon. Watson-Williams was in charge of the combined department until 1921; he was also lecturer in charge of the department of laryngology and otology at the University of Bristol from its inception until 1922. On attaining the age limit he relinquished his hospital and university appointments, but continued in active practice up to the time of his death.

As with some others during the evolution of oto-rhino-laryngology, Watson-Williams, having started his career as a general physician with an interest in diseases of the larynx, had to change to an operating surgeon, which change he carried out with such success that he achieved an international reputation in his specialty, particularly in association with the diagnosis and operative treatment of diseases of the nasal sinuses and of their importance in general medicine. His courage and enthusiasm are shown by the fact that he was also one of the founder members of the old Laryngological Society of London, helping his distinguished senior colleague and friend Sir Felix Semon in the formation of this society, which subsequently became the Laryngological Section of the Royal Society of Medicine. Watson-Williams was one of the earlier presidents of this section, and at the meeting in Bristol in 1911, during his year of office, the establishment of the Semon Lectureship in Laryngology in the University of London was announced. This lectureship was founded largely by the efforts of Watson-Williams in recognition of the services which Semon had rendered to the advancement of the new specialty. He was appointed Semon Lecturer in 1925, and took as his subject "The Toll of Chronic Nasal Focal Sepsis on Body and Mind." In 1911 he represented

the Royal Society of Medicine at the Berlin International Laryngological Congress, and was *président d'honneur* at the first International Congress for Tuberculosis in Paris. During the war he served as a major in the R.A.M.C.(T.) at the Second Southern General Hospital, and was appointed consultant for diseases of the ear, nose, and throat to the Southern Command.

Watson-Williams was a man of boundless energy. In his native city Bristol he not only took a prominent part in the organization and advancement of his department at the Royal Infirmary, but he was also for twelve years assistant editor of the *Bristol Medico-Chirurgical Journal*, and for a further fourteen years, from 1912 to 1926, its editor. His eminence in the profession, as well as his work for the University, was recognized in 1932 by the conferment upon him of the honorary degree of M.D. in the University of Bristol.

His life work may be summed up into three periods. The initial phase was that of the physician taking an interest in laryngology, and particularly in helping it to evolve into a recognized specialized branch of surgery. In the second phase, having appreciated the wide possibilities open to the laryngologist by the evolution of modern surgery, he threw himself with extraordinary perseverance, ingenuity, and intelligence into the elaboration of the technique of operations, particularly those designed for the treatment of infections of the nasal accessory sinuses. As a result of this phase of his work instruments and methods devised by him are in use in all parts of the world. The third phase is represented by a combination of the outlook of the general physician and the operating surgeon. Here he set himself to emphasize the neglected close association between infection, particularly in the region of the nose and throat, and general constitutional disease, his opinions on this subject being well in advance of his time. He has left behind him many contributions to medical literature, and, apart from articles in the various journals, he wrote a textbook, *Diseases of the Upper Respiratory Tract*, and articles on diseases of the nose, throat, and trachea in Clifford Allbutt's *System of Medicine*. More recently, as evidence of the third phase, he wrote a book, *Chronic Nasal Sinusitis and its Relation to General Medicine*. As an artist he was highly accomplished, evidence of this gift being furnished by the many illustrations in his work which emanated from his own pencil. It was a real pleasure to watch him rapidly sketch pathological conditions which he might be demonstrating.

Patrick Watson-Williams was a man of considerable charm of manner and of bountiful hospitality. While he never failed to give of his own experience and opinions, he always received courteously the views of others. He leaves a widow, the daughter of the late Dr. Long Fox, an eminent Bristol physician in whose memory a lectureship has been founded; and one of his sons, Eric Watson-Williams, is in charge of the department which his father founded at the Bristol Royal Infirmary.

A. J. W.

[The photograph reproduced is by Elliott and Fry, Ltd.]

The following well-known foreign medical men have recently died: Dr. ERNEST MALVOZ, an eminent medical sociologist of Liège, aged 76; Dr. ALONZO GALE HOWARD, emeritus professor of orthopaedics at the Boston University School of Medicine, aged 68; and Dr. PAUL STRASSMANN, an eminent Berlin gynaecologist, aged 72.

JANE WALKER, C.H., LL.D., M.D.

Founder of the Medical Women's Federation; Medical Superintendent, East Anglian Sanatorium, Nayland

Dr. Jane Walker died at her home in Harley Street on November 17 at the age of 79. Dr. Walker was well known as one of the pioneers of the open-air treatment of tuberculosis, and was perhaps the oldest medical woman still in practice in this country. She remained at work until a few days before her death.

Born in Dewsbury, Yorkshire, on October 24, 1859, Jane Harriett Walker was educated at Southport and at the London School of Medicine for Women. She took

the L.R.C.P.I. and L.M. in 1884, and the L.R.C.S.Ed. in 1889. She continued her studies abroad, and became an M.D. of Brussels in 1890, at a time when she could not have obtained a doctorate in medicine from any British university. She was always interested in paediatrics, and acted as a clinical assistant at the East London Hospital and later as resident medical officer to the Wirral Children's Hospital. She was later in general practice for a while, but the work by which she will be remembered

began in 1892. A visit to the Nordrach Colony in the Black Forest, which had been founded in 1888, made her one of the early advocates of the open-air treatment of tuberculosis. Advocacy became action in 1892, when she took a farmhouse at Downham Market, Norfolk, and created there a small sanatorium. This centre, which began with only six beds, developed rapidly, a small home for paying patients being opened in a neighbouring village, and in 1901 was transferred to Maltings, near Nayland, Suffolk, as the East Anglian Sanatorium. To this sanatorium a department for the poorer members of the community was added in 1904; a ward for children in 1912; a section for tuberculous soldiers in 1916, and for officers in 1919.

Dr. Jane Walker was a woman of great energy and force of character, with many interests in life both within and outside her profession. She was a founder and for a long time treasurer of the Medical Women's Federation, and afterwards its president and honorary secretary. She had been physician to the Elizabeth Garrett Anderson Hospital; a member of the Departmental Committee on the provision for treatment of tuberculosis (the Astor Committee); and she served on the West Suffolk Agricultural Committee and other public bodies. She wrote numerous articles on social questions of the day, and published a book, *The Modern Nursing of Consumption*, which reached a second edition in 1924, and a *Handbook for Mothers*. She was one of the early suffragists, and for eighteen years treasurer of the Association for Moral and Social Hygiene. Her outstanding services to medicine and the community were recognized in 1931 by the award of the Companionship of Honour; in the same year she received the honorary degree of LL.D. from the University of Leeds. Dr. Walker joined the British Medical Association forty-five years ago, and was vice-president of the Section of Tuberculosis at the Portsmouth Annual Meeting in 1923. She was also a regular attendant at the meetings of the Joint Tuberculosis Council.

In October, 1939, Dr. Jane Walker would have been 80, and would have been able to celebrate the diamond jubilee of her entry into medicine. A scheme was on foot to establish in celebration of this event a Jane Walker Juvenile Research Clinic at Nayland.

Lady Barrett, C.H., M.D., writes:

With the passing of Dr. Jane Walker another pioneer for the equal rights of men and women has left us. Liberty and opportunity for the development of the inherent powers in every human being were the aims for which she strove, and difficulties and opposition but fed in her the will to achieve. It was natural therefore that politically she stood with the Labour Party, and in foreign affairs her sympathy was with the right of small nations to retain their freedom. Others will doubtless speak of her life-work in tuberculosis and the introduction of occupational therapy in her sanatorium for sufferers after the war. It may surprise some, who met her only in the worlds of medicine and politics, to realize that in the life of this active fighter there was time for a very real appreciation of the arts, especially music and painting. A lovable friend was Jane Walker, who could swear at you at one moment and grasp your hand in real and eternal friendship the next.

[The photograph reproduced is by Elliott and Fry, Ltd.]

A. BOSWORTH WRIGHT, J.P., M.R.C.S.

We announce with regret the death on November 9 of Dr. A. Bosworth Wright of Southsea. Alfred Bosworth Wright was born at Wellingborough on July 11, 1872, son of the late Dr. Brampton Wright. His family moved to Southsea, and he was educated at the Portsmouth Grammar School, entering the London Hospital in 1890, where, after qualifying M.R.C.S., L.R.C.P., he became house-physician, receiving-room officer, and house-surgeon. He started practice in Southsea and became a member of the British Medical Association in 1899. When the Royal Portsmouth Hospital was reorganized he was appointed assistant surgeon, a post he held from 1900 to 1908, when he became full surgeon. With the late C. P. Childe and Munro Ford the surgical work of the Royal Portsmouth Hospital rapidly went forward, and Bosworth Wright took his full share in its development. In spite of a large general and surgical practice he found time to do much hospital surgical work, and his cheerful disposition and general good fellowship made him deservedly popular with everyone.

Dr. Wright was an original member of the Portsmouth Rotary Club and later became its president, but he was chiefly known for his great interest in the Boys Club and the boys' work generally. He entered public life in 1920 as a member of the Portsmouth City Council, and became Alderman in 1935. From 1922 to 1923 he was president of the Southern Branch of the British Medical Association, and in 1923 was vice-president of the Section of Obstetrics and Gynaecology at the Annual Meeting at Portsmouth. Owing to the twenty years' rule for full surgeons at the Portsmouth Hospital he had to retire from the active staff at the early age of 56, but he threw himself with energy into the work of transforming the Poor Law infirmary into a modern general hospital—St. Mary's Hospital, of which he was governor. His splendid physique began to show signs of strain, and two or three years ago he was ill for some weeks with threatening heart trouble. It was obvious that he was working at too great a pressure, and the end came suddenly after a short illness of about a day and a half. Ever ready to do a kindness and

to help any of his professional brethren, or indeed anyone in Portsmouth, he will be greatly missed, and his experience and skill will be difficult to replace, particularly in the work of the city council, to which he gave so much of his time. There was a large and representative gathering at Portsmouth Cathedral on November 12 to pay its last respects to a colleague greatly loved and greatly missed. He leaves a widow, to whom much sympathy has gone out.

Dr. A. E. Sears of Milford-on-Sea writes:

My knowledge of and friendship with "A. B. W." extend over forty-eight years, from the time when we entered the London Hospital as students together in 1890. The outstanding feature of his personality was his lovable disposition, which embraced all classes, and his detestation of all shams and affectations. His never-failing sense of humour, his cheerful and hearty manner, and, above all, his transparent honesty, made him trusted and respected by all who knew him. He always had a touch of the seaman's roll in his walk, and his leisurely progress down the streets was interrupted by frequent cheeks. Perhaps it was an urchin who sold papers and who was addressed as "George" or "Bill" with an inquiry as to "how business was," or an elderly matron in a small shop to ask after the health of herself or her family. In fact, progress was so slow that he would be left while his companion hurried on to the evening meal, to which Wright would return when food and plates were almost cold, with apologies to the landlady and the cheerful assurance that he preferred a lukewarm dinner. From class-consciousness he was entirely free, and though he was a respecter of persons entitled to regard by reason of their abilities or personal attributes, his manner to the pretentious was one of good-humoured tolerance. In short, "A. B. W." was a big man with a big heart, with a shrewd insight into character and a belief in the innate goodness of his fellow men, which sprang from the greatness of his own individuality.

We regret to announce the death on November 12 of Dr. ETHEL STACY of Bedford. Dr. Stacy studied medicine at the London School of Medicine for Women, and qualified L.S.A. in 1902 and M.B., B.S. Lond. in 1904. She had been a member of the British Medical Association for thirty-five years. A colleague writes: Dr. Ethel Stacy established herself as a general practitioner in Bedford when a woman still needed something of the pioneer spirit in order to engage in the practice of medicine, especially in the provinces, and the same spirit informed her many activities in the town of her adoption. She took a prominent part in organizing the first infant welfare centre in Bedford, which was later taken over by the town council, and an active interest in the Bedford District Nursing Association, the County Red Cross Association, and the Bedford and County Girls' Home, of which she was for many years honorary medical officer. She also found the time to sit on the Maternity and Child Welfare Subcommittee of the British Medical Association, and on the Board of Governors of the East Anglian Sanatorium, Nayland. Her determined optimism, sound common sense, complete disregard of self, and refreshing unconventionality of outlook made her a most valued member of committee as they made her a most valued friend, and in either sphere she never refused any call that was made upon her. As a family doctor she had a remarkable power of absorbing all the details of her patients' daily lives and surroundings, and never lost sight of the patient in treating the disease or failed to treat the patient because the disease was incurable. Her own optimism was of a quality which could scarcely fail to communicate itself even to the most severely ill. As physician, as friend, and as a worker in all good causes she leaves a place that cannot be filled, and her untimely death will be deeply mourned.

Medical Notes in Parliament

Business set down for the House of Lords this week included the Marriage (Scotland) Bill. The House of Commons considered the possibility of aiding refugees, and Palestine policy was down for discussion.

The Parliamentary Medical Committee met at the House of Commons on November 21, Sir Francis Fremantle in the chair, and sent a message of sympathy to Dr. Salter, who had been ill. Dr. Hill, Deputy Secretary of the British Medical Association, attended the meeting and gave an account of the efforts by the Association in the past eighteen months to prepare the part of the medical profession in air defence. He stated that a few weeks before the recent crisis 95 per cent. of the profession accepted further obligations. The Government had now undertaken to keep up the register then compiled. Dr. Hill pointed out deficiencies which required to be made good in the national preparations for the use of medical men's services and the need for co-operation between Government Departments. The Committee showed its interest in the motion on these matters, which is to be moved by Sir Francis Fremantle in the House of Commons on November 30.

Dr. Elliot has accepted an invitation to dine with the Parliamentary Medical Committee at the House of Commons on December 14. Former members of the Committee will also be invited.

Major B. H. H. Neven-Spence has become Parliamentary Private Secretary to Dr. Elliot.

The annual reports of the National Radium Trust and Radium Commission for 1937-8 have been presented to both Houses.

New Bills

The Voluntary Hospitals (Relief from Rating) Bill proposes that notwithstanding anything contained in any local or general Act of Parliament no body or person shall be liable to pay rates in respect of any lands or buildings used for the purposes of a voluntary hospital. "Voluntary hospital" is defined as an institution, not being an institution which is carried on for profit or which is maintained wholly or mainly at the expense of the rates, which provides medical or surgical treatment for in-patients. The Bill does not extend to Scotland or Northern Ireland.

The Expiring Laws Continuance Bill was introduced in the House of Commons on May 16.

Mental Reform Bill: Proposals for Mental Cases

The text of the Criminal Justice Bill was issued on November 16. This measure has been introduced by Sir Samuel Hoare. The following are its proposals concerning mental cases.

Clause 38 proposes to give improved facilities to courts of summary jurisdiction in England and Wales to obtain a medical report on the mental condition of an offender in order to assist the court in deciding how to deal with him. At present such a report can be obtained if the offender is remanded to prison, but it may be difficult for a court to obtain such a report otherwise. The clause enables the court to remand an offender on bail with a requirement that he submits himself to medical examination, and provides for payment of the cost of medical examinations at approved institutions or by approved persons. This clause does not apply to Scotland.

If an offender is certifiable as a mental defective the court, in lieu of sentencing him, may, under the existing law, make an order for him to be dealt with as a mental defective. If an offender is certifiable as insane, a court of summary jurisdiction in England and Wales has no similar power. Clause 39 will enable courts of summary jurisdiction to make an order for the treatment of an offender who is certifiable as insane in the same way as they can at present make an order for the treatment of an offender who is mentally defective. This clause does not apply to Scotland.

There are offenders who, though not certifiable as insane or mentally defective, are suffering from some form of mental illness or abnormality which is susceptible to treatment. Clause 19 provides that probation orders may include a provision requiring such persons to submit themselves to mental treatment, and Clause 6 enables payment to be made for such treatment as part of the expenses of probation committees. These clauses do not apply to Scotland.

Persons who, when committed for trial on indictment, are found to be insane on arraignment or are found guilty but insane, and persons certified insane while serving a term of imprisonment or penal servitude, become "criminal lunatics" and are liable to detention in the State Criminal Lunatic Asylum at Broadmoor or a mental hospital. Analogous provisions are in operation in Scotland. It is proposed by Clause 67 to substitute for the term "criminal lunatic" the term "State mental patient," and to call the State institution at Broadmoor the Criminal Lunatic Department of Perth Prison, and the State Asylum now being built in Lanarkshire, "State Mental Hospitals."

It is also proposed by Clause 68 to transfer the responsibility for the control and management of the Broadmoor institution to the Board of Control, which is the authority responsible for the management of the State institution for mental defectives and for the supervision of all mental institutions in England and Wales. The responsibility as regards the discharge from custody of State mental patients will still remain with the Secretary of State.

STATE REMAND HOMES

On Clause 11 the following explanation is furnished:

In addition to the remand homes provided at present by local authorities under the Children and Young Persons Acts for persons under 17, there is need for special remand homes for "problem" cases of children and young persons under 17 requiring special medical observation. The number of such cases arising in the area of any one local authority is limited, and such a special remand home will serve a large region comprising many local authorities. In view of the difficulty of arranging for local authorities to provide such a regional institution, it is proposed by Clause 11 to authorize the Secretary of State to provide such places, and to preserve the existing financial arrangement under which the cost of remand homes is divided between the Exchequer and local authorities, by requiring the local authorities using the State remand home to contribute to the cost. This clause does not apply to Scotland.

CORPORAL PUNISHMENT

Clause 32 proposes to give effect to the recommendation of the Departmental Committee on Corporal Punishment that the existing powers of the courts to pass sentences of corporal punishment should be abolished.

Clause 47 gives effect to the Committee's recommendations for amending the law relating to corporal punishment as a method of dealing with certain serious prison offences.

Other clauses deal with the treatment of young offenders, the classification of prisoners, and other ameliorations of the penal system.

Milk Industry Bill

Mr. W. S. Morrison introduced the Milk Industry Bill on November 16.

Part I provides for the constitution of a Milk Commission and of a Milk Advisory Committee.

Part II provides, in respect of the period ending September 30, 1943, for the offer of increased inducements by milk marketing boards, with the assistance of substantial Exchequer contributions, for the provision of cleaner and purer milk. It is proposed that these provisions shall operate retrospectively as from October 1, 1938, and in anticipation of this the Milk Marketing Board for England and Wales and the Scottish Milk Marketing Board have already made arrangements, so far as practicable, for paying increased rates of premiums corresponding to those foreshadowed in the white paper on milk policy on the designated milks concerned and milk from attested herds.

Part III of the Bill extends until the end of September, 1943, the period during which Exchequer assistance will be available to enable milk marketing boards to operate the milk-in-schools schemes, and the proposed schemes for the provision of milk at reduced prices for nursing and expectant mothers and young children.

Part VII of the Bill enables the Minister of Health or the Department of Health for Scotland to make pasteurization orders on the application of a local authority, if the Minister or Department, after consultation with the Milk Commission, is satisfied that it is proper in the circumstances so to do having regard to the needs of consumers and the interests of retailers in the area. Such orders will prohibit, after a specified date, not earlier than two years after the making of the order, the sale by retail in the area concerned, for human consumption, of milk that is not either pasteurized, sterilized, tuberculin tested, or certified. Provision is, however, made for securing that retailers in the area who obtain 80 per cent. of their supplies from a single herd may secure exemption for such milk for a further three years after the prohibition would otherwise operate. A local authority that intends to apply for an order is required to give at least four weeks' notice of its intention, and provision is made for an inquiry into objections to the making of any order. A pasteurization order may, with necessary adaptation, extend also to cream.

Part VIII of the Bill provides for the co-ordination of expenditure by the various sections of the industry on research.

Road Accidents and Speed Limit

A motion viewing with concern the continued high rate of road accidents and calling for more effective action for the public safety was moved on November 16 by Mr. F. C. Watkins. Mr. WATKINS said that during the past ten years 70,000 people had been killed and more than 2,000,000 injured on the roads. Over a number of years one in every seven of the people killed had been either 5 or 6 years of age. Nearly a quarter of the injured were boys and girls. The Ministry of Transport analysis of accidents showed that where there was a facility for increased speed, however good the lighting and the surface, people were killed and the hospitals received the injured.

Mr. BURGIN said the statistics of the Registrar-General showed some 20,000 fatal accidents in a year from a variety of causes. Deaths on the roads were the shocking figure of 6,000 or 6,500. Deaths on the roadways of the United States in 1937 were over 40,000 and in Germany approximately 8,000. Of road accidents in Great Britain involving persons injured 70 per cent. occurred in daylight, 4 per cent. in dusk, and the rest in the dark. Of all accidents 76 per cent. happened in areas where there was a speed limit, because accidents and congestion were two aspects of the same problem. The human factor was and would remain the principal cause of accidents.

The House carried without a division the motion proposed by Mr. Watkins.

Abolition of the Death Penalty

On November 16 Mr. VVYAN ADAMS moved a motion declaring that the House of Commons would welcome legislation by which the death penalty would be abolished in time of peace for an experimental period of five years. He said that yearly, in the past decade, fifty-five persons were charged with murder, excluding infanticides, which on the average numbered about fifteen. Twenty was a normal yearly figure for death sentences, and as a rule fewer than ten were executed. Juries were frequently reluctant to convict on capital charges and might return a verdict of "Guilty but insane." Lord Darling, giving evidence before the Select Committee on the Abolition of the Death Penalty, had said: "I have heard several people in charge of criminal asylums say that there are several people in the asylums as sane as the judges who tried them."

Mr. MAXWELL FYFE moved the rejection of the motion. Mr. GEOFFREY LLOYD said this was the first occasion on which the House had been asked to declare itself in favour of an experiment of this kind. The only recent occasion on which capital punishment was debated in Parliament was in 1929. As a result a Select Committee was set up on the subject. The report of that committee contained a recommendation in the terms of the motion moved by Mr. Vyvan Adams, but that report was presented after six members of

committee had withdrawn. It could not be accepted as expressing the views of representative members of all parties in the House. Mr. Lloyd added that there was no support, in the experience of the Home Office, for the presumption that juries in murder cases were reluctant to convict.

Mr. Vyvyan Adams's motion was carried by 114 to 89.

Insurance Practitioners and Postgraduate Courses.—On November 14 Dr. Elliot informed Mr. Roston Duckworth that fifty-eight of the insurance practitioners practising in England attended a short series of experimental courses of postgraduate medical instruction in the autumn of 1937, and 862 would have attended courses this year when the current programme was completed this month.

Medical Certificates.—On November 14 Mr. RIMS DAVIES asked the Minister of Health if he was aware that although panel doctors received the same fee of 9s. per annum in respect of young persons between 14 and 16 years as for those between 16 and 65, some of them charged a fee for medical certificates for the first category when required for claiming benefit from sources other than national health insurance, though they were compelled to issue certificates for the second category for the same panel fee. Dr. ELLIOT replied that an insurance practitioner was obliged to give medical certificates without charge only if they were required for the purposes of national health insurance. He was entitled to make a charge for a certificate which was not required for those purposes, whether in respect of a juvenile contributor or of an adult insured person.

Vaccination Fees.—Mr. LEACH asked, on November 10, under what Act of Parliament or Ministerial Order a borough council acted when paying vaccination fees to persons other than public vaccinators and vaccination officers. Dr. ELLIOT, in reply, said the Public Health (Small-pox Prevention) Regulations, 1917, authorized the payment of fees to medical officers of health for the vaccination and revaccination of contacts. The Vaccination Order, 1930, empowered local authorities to appoint "assistants" to vaccination officers.

Medical News

The annual reunion dinner of the London (Royal Free Hospital) School of Medicine for Women will be held at the Savoy Hotel on Thursday, December 1, at 7 for 7.30.

The annual dinner of the Westminster Hospital Medical School, which was postponed from October 1, will be held at the Trocadero Restaurant, Piccadilly, W., on Tuesday, December 13, at 7.30 for 8 p.m. with Dr. Adolphe Abrahams, dean of the medical school, in the chair.

The next dinner of the Oxford Graduates Medical Club will be held on December 16 at the Langham Hotel, London, when the chair will be taken by Mr. H. S. Souttar. The price of tickets is 12s. 6d. each person (exclusive of wine). Further information may be obtained from the honorary secretary, Mr. E. A. Crook, 99, Harley Street, W.1.

A dinner will be held on November 29 at the Savoy Hotel, London, in aid of funds for the Institute for the Scientific Treatment of Delinquency. The chair will be taken by Viscount Hailsham, and the speakers will be the Lord Chancellor, Viscount Samuel, Lord Roebuck, Mr. St. John Hutchinson, and Dr. Denis Carroll. The Institute is entirely dependent on voluntary contributions, and funds are urgently needed both for the maintenance of existing activities and for future research work. Tickets, 30s. each, may be obtained from the chairman of the dinner committee, the Countess De La Warr, 20, Chester Square, S.W.1.

The second annual dinner of the London Manchester Medical Society will be held at the Trocadero on Thursday, December 8, at 7.45 for 8 p.m. Tickets (12s. 6d. each) are obtainable from the secretary, Mr. Albert Davis, 93, Harley Street, W.1, from whom further particulars may be obtained.

Work on the northern wing of the British Medical Association's new building has now begun and it has been necessary to put the existing garage out of action until the completion of the new car accommodation to be provided in the basement. The loss of this garage renders the task of parking cars at B.M.A. House a difficult one, and members visiting the House and attending meetings are asked to co-operate with Headquarters by refraining from using their cars whenever it is possible, in order to relieve the congestion.

The Lord Chancellor has appointed Dr. Albert Edward Evans, a Commissioner at the Board of Control, to be a Chancery Visitor of Lunatics, in the place of Lieutenant-Colonel Nathan Raw, C.M.G., M.D., who has retired.

In our advertisement columns this week the University of London invites applications for (a) the University Chair of Medicine tenable at University College Hospital Medical School, and (b) the University Readership in Medicine tenable at the British Postgraduate Medical School. The salaries attached to the posts are £2,000 per annum and £800 per annum respectively.

The annual dinner of the Old Epsomian Club will be held at the Café Royal, Regent Street, W., on Thursday, December 8, at 7 for 7.30 p.m.

The Glasgow University Club, London, will dine at the Café Royal, W., on Friday, December 2, at 7.15 for 7.30 p.m., with Mr. W. Craig Henderson, K.C., D.Sc., in the chair. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the honorary secretaries, 62, Harley House, N.W.1.

A meeting of the Listerian Society of King's College Hospital will be held at the hospital (Denmark Hill, S.E.) on Wednesday, November 30, at 8.30 p.m., when Sir Harold Gillies will give an address on "Plastic Surgery," and will show cases and films. Dr. W. Sheldon will occupy the chair.

The German clinics in Prague which were closed at the time of the occupation of the Sudeten districts have been reopened under the direction of Professor W. Nonnenbruch.

The Society of Chemical Industry celebrated on November 24 the centenary of Sir William Perkin, the discoverer in 1856 of the first aniline dyestuff, mauve.

On November 10 Queen Mary paid a visit to the new premises of the Children's Centre, Institute of Child Psychology. She was received by the vice-chairman, Dr. Hazel Chodak Gregory (in the absence through illness of the chairman, Professor Winifred Cullis). The two honorary directors, Dr. Margaret Lowenfeld and Dr. Ethel Dukes, accompanied Her Majesty on a tour of the building and explained to her the work of the Institute. In the play-therapy department the special methods of treatment were demonstrated to her. She paid visits also to the physical re-education and rhythm department, and observed intelligence tests in progress.

Major B. H. H. Neven-Spence, R.A.M.C. (ret.), has been appointed Parliamentary Private Secretary to the Minister of Health in the place of Mr. Allan Chapman.

EPIDEMIOLOGICAL NOTES*

Typhoid at Shoreditch

In the late afternoon of November 9 information of three cases of typhoid fever was telephoned to the Public Health Department at Shoreditch with a statement that two relatives of the patients were at home with similar symptoms. Inquiries at the patients' homes were put in hand forthwith and the Ministry of Health and the London County Council were notified that evening. Since that time the Public Health Department has been continually in touch with medical officers at the Ministry and has been greatly assisted by the advice and co-operation of Dr. Norman Smith. Further cases of typhoid fever have occurred or have been discovered since that date, and the position at midday, November 23, was that 24

* Except where otherwise mentioned, figures in parentheses refer to the week preceding the one under review.

cases had been notified as occurring in the borough among borough residents, 2 cases in persons working in the borough but living outside, and 1 case in a child living in Essex who came into the borough one evening a week to visit relatives who are among the borough cases. One patient had died. Medical practitioners in the borough and surrounding medical officers of health were informed of the position on Thursday, November 10, and one or two doctors who made inquiries were told that if they wished to vaccinate contacts the cost would probably be paid by the borough council. Serum was not considered advisable. Medical practitioners were further informed as to the position on the following Tuesday, and a meeting was called for the Wednesday afternoon to discuss further means of mutual co-operation. Here, with the authority of the Public Health Committee, it was agreed to have available for contacts and other suitable persons a scheme for vaccination, to be run on similar lines to the British Medical Association's diphtheria immunization scheme. Detailed inquiries suggested almost from the beginning a common source of infection through ingested foodstuffs, and events which have subsequently occurred have served to strengthen this belief. It is understood that the turnover in the sale of foodstuffs which might possibly be the vehicle for spreading infection is such that little was likely to remain unsold for more than a week, and probably none for more than a fortnight. As the date of first infection was about the middle of October the originally infected foodstuff had been disposed of before the first cases were notified. Unfortunately it has not yet been possible to trace the actual person or source responsible for the contamination, although detailed personal and family histories have been obtained from possible food-contacts and some thirty bloods tested for Widal reactions. Much work has had to be done to eliminate other sources of infection, including the water supply, milk supply, and certain other foods. The variability of the incubation period is another difficulty in differentiating between primary and secondary cases, of which latter, owing to the poorness and congestion of some of the infected houses, there are likely to be further cases during the next week or so.

Poliomyelitis

In the week under review the greatest fall, from 70 to 51, has been recorded since the present epidemic began in the first week of July. The disease remains widespread in a rather sporadic fashion. As regards the 51 cases notified in England and Wales, the counties chiefly affected were: Southampton 5 (Bournemouth 1, Eastleigh 1, Petersfield 1, Ringwood and Fordingbridge 1, Southampton 1); Leicester 4 (1 in Leicester and 3 in the administrative county); Durlam 3 (Billingham 1, Ryton 1, Stockton 1); Kent 3 (1 each in Orpington, Sevenoaks, and Maidstone); Lincoln 3 (Scunthorpe 2, Welton 1); London 3 (1 each in Deptford, Lewisham, and Southwark); Oxford 3 (Oxford 2, Witney 1); Surrey 3 (Epsom and Ewell 2, Beddington and Wallington 1); Sussex 3 (Cuckfield 2, Horsham 1); Yorks N. Riding 3 (Guisborough 2, Richmond 1); Glamorgan 3 (all in Cardiff). Of the cases in Scotland, 1 each occurred in Glasgow and Edinburgh. During the week ended October 22 the number of cases of poliomyelitis in Germany (excluding Austria) was 342, compared with 364 in the previous week; increases were recorded in Saxony 50 (39) and Hessen 19 (7). In Austria the number rose from 13 to 19. During the week under review 250 cases were recorded in Germany; there was a decline in the disease in all parts of the country except Baden, where notifications rose from 24 to 28. During the week 28 cases were reported in Holland: 15 in the Province of South Holland (10 in the Rotterdam district) and 6 in the district of Harlingen. In Denmark during September 92 cases were recorded: 15 in the Aalborg district and 17 in the district of Hjøring. During the same period 99 non-paralytic cases were recorded: 12 each in the districts of Aalborg and Hjøring and 10 in the district of Odense (Jutland). In the first fortnight of October 165 cases were recorded in Sweden, of which 37 were

non-paralytic, compared with 162 (66 non-paralytic) in the preceding fortnight. Of the 165 cases, 53 occurred in the rural district of Jämtlands, 26 in the rural district of Kristianstads province, and 13 in Västernorrlands.

Primary and Influenzal Pneumonia

In England and Wales a considerable increase was recorded: 799 as against 583, the figures for London being 97 as against 75. Deaths fell from 37 to 28 in the Great Towns, and in London from 7 to 1. The counties principally affected were: Lancaster 125 (Manchester 47, Liverpool 24); London 97 (Stepney 11, Poplar 9, Lambeth 8); Durham 49 (Sunderland 17); Essex 39; Warwick 38 (32 in Birmingham); Yorks West Riding 78 (Sheffield 23, Leeds 14). There were 5 deaths from influenza in Birmingham, 3 in Manchester, 2 in Sheffield, 2 in Walsall. Notifications of primary pneumonia in Scotland rose from 272 to 367; the centres principally involved were Glasgow 234 (183); Dundee 21 (9); Lanark Co. 21 (10); Aberdeen 13 (9); Port Glasgow 10 (0). During the week there were 6 deaths from influenza in the 16 Great Towns—5 in Glasgow and 1 in Edinburgh.

Diphtheria and Scarlet Fever

A very small decrease in the notifications of diphtheria was recorded in England and Wales during the week: 1,445 compared with 1,457, and in London 141 compared with 145. The chief centres affected were London 141 (Lambeth 18 (9), Poplar 11 (16), St. Pancras 9 (2), Camberwell 9 (8)); Birmingham 35 (24); Bristol 31 (33); Sheffield 26 (26); Liverpool 26 (48); Leeds 23 (31); Cardiff 18 (9); Easington 18 (21); South Shields 15 (25). Of the 23 deaths from diphtheria in the Great Towns of England and Wales, 4 were in Liverpool, while in no other town did more than 1 death occur. In Scotland notifications of diphtheria rose from 253 to 291; the principal centres affected were Glasgow 97 (77); Lanark Co. 20 (18); Edinburgh 18 (15); Renfrew Co. 16 (13); Aberdeen 14 (18). One death (in Glasgow) was reported.

There was a fall in the incidence of scarlet fever in England, Wales, and Ireland, and a rise in Scotland from 403 to 435. The principal towns affected were London 170 (Wandsworth 17 (13), Stepney 14 (13), Camberwell 12 (8), Lambeth 12 (11)); Liverpool 51 (62); Bristol 38 (33); Birmingham 37 (38); Manchester 34 (28); Portsmouth 33 (18); Leeds 28 (28); Sheffield 26 (25); Stoke-on-Trent 26 (31). There was one death (in London).

Measles and Whooping-cough

Twenty-five cases of measles were notified in London during the week compared with 22 in the previous week. More than 2 cases were notified in St. Pancras 4 and Stepney 3. There was one death in Dagenham. In Scotland 32 cases were notified and there were no deaths. In London notifications of whooping-cough rose from 141 to 145. The chief boroughs affected were Kensington 13, Stepney 12, St. Pancras, Islington, Poplar, and Wandsworth 11 each. Of the 169 cases of whooping-cough notified in Scotland 225 (158) were in Glasgow, 14 (11) in Paisley, 8 (4) in Greenock, and 8 (11) in Edinburgh. All three deaths reported were in Glasgow.

Cholera and Plague

During the week under review there were 391 (418) cases of cholera and 204 (229) deaths in the Central Provinces of India. 250 cases (324) and 105 (136) deaths in Bombay Presidency, and 210 cases (104) and 108 (51) deaths in the United Provinces.

In British India during the same week there were 186 (155) cases of plague with 19 (13) deaths in the Central Provinces, and 33 (30) cases and 14 (15) deaths in Bombay Presidency, and 86 (43) cases and 67 (31) deaths in Burma. Reports have come to hand of a severe outbreak of bubonic plague in the Gorlos Southern Banner district between Hsinking and Taonan. The outbreak started at the beginning of October, and by the 24th of the month over 250 fatal cases had been reported, the mortality rate being 99 per cent.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended November 12, 1938.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Death, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns (124 in 1937) in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases: a blank space denotes disease not notifiable or no return available.

| Disease | 1938 | | | | | 1937 (Corresponding Week) | | | | | 1929-37 (Median Value Corresponding Weeks) | |

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS.—All communications should be addressed to the Advertisement Manager (office hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are

EDITOR OF THE BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

SECRETARY, *Medisecra Westcent, London.*

The address of the B.M.A. Scottish Office is 7, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh), and of the Office of the Cumann Doctúir na h-Eireann (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone 62550 Dublin.)

QUERIES AND ANSWERS

Hypertonia in Post-encephalitic Parkinsonism

Dr. E. W. DEWEY (Portsmouth) writes: I should be grateful for suggestions for the relief of muscular hypertonia occurring in a case of post-encephalitic Parkinsonism. My patient has arthritis as well, and the combination is a peculiarly distressing and disabling one, but the symptom that seems to trouble her most at present is a painful stiffness of certain groups of muscles, particularly the quadriceps, which renders sitting or remaining in one position for any length of time almost intolerable. There are no actual contractures or obvious cramps.

Varicose Veins

Dr. DANIEL M. RAYNES (London, S.W.1) writes in answer to "M. E. D." (*Journal*, November 19, p. 1070): I have had a similar case of a female patient who, according to her own account, had had numerous varicose veins of long standing injected by her previous doctor with great success. However, two very large veins, one in each leg, proved very resistant to repeated injections of various preparations. I injected each of them once, using 2 c.cm. of a 5 per cent. sodium morrhuate (B.D.H.) solution, without any result. On her return a week later it occurred to me that, since all sclerosing materials must of necessity irritate the endothelial lining of the vein before the desired thrombosis can occur, it would be useless to continue the injections unless the irritating material came into actual contact with the endothelium in that part of the vein where occlusion was desired. Accordingly I arranged for the patient herself to apply gentle but moderate pressure over the most dependent parts of the vein by means of a pad of cotton-wool that I placed along the course of that vein; this left exposed only the uppermost part of that vein, where I injected 2 c.cm. of the same solution. The patient was instructed to keep up the gentle pressure until, after withdrawing the needle and sterilizing the site of the puncture, I fixed the same pad by means of an elastoplast bandage applied fairly firmly round that part of the leg where the varicose vein was prominent. This technique apparently prevented the irritating fluid from either dropping down the drain, as it were, to where it was not required, or from becoming diluted in the comparatively large amount of blood in the previously uncompressed vein. To my amazement, on the patient's return a week later there was hardly a trace of either of the long-resistant veins after only a single injection into each one of them.

Dr. F. RYLANDS (Manchester) also writes: The quinine fails to act because in the large veins the solution is washed

away by the blood stream before it has acted on the endothelium. I would suggest that "M. E. D." should try injections with sodium morrhuate, 10 per cent. instead of the usual 5 per cent., giving 2 c.cm. at each injection. A useful tip in resistant cases is to move the needle carefully from side to side while injecting the solution within the vein.

Cattle Ringworm in Man

Dr. T. J. HOLLINS (Battle, Sussex) writes in answer to Dr. Stewart (*Journal*, November 12, p. 1027): I have found "mitigal" (Bayer) practically a specific in such cases. I paint it on each day with a camel-hair brush, and cover with a simple dressing. After five or six applications the ringworm disappears. With the permission of a local farmer I treated some calves that had well-marked ringworm. In every case it cleared up after a few applications.

Case for Diagnosis

"NEMO" writes in reply to Dr. E. S. Hawkes (*Journal*, November 19, p. 1070): I would suggest that if the rise in temperature follows the midday meal it would be advantageous to have an x-ray photograph of his patient's teeth, because root sepsis might account for the condition. In many families this meal more than any other includes butcher's meat; and as such food generally requires more mastication than other, vigorous mastication might be responsible for driving pus into the lymphatics, and so setting up a condition such as he details.

LETTERS, NOTES, ETC.

Suppression of Lactation

Dr. FREDERIC SANDERS (London, E.4) writes: In the *Journal* of October 29 (p. 887) is a paper by Drs. G. L. Foss and P. Phillips advocating oestrone for the suppression of lactation, and in that of November 5 (p. 944) an article by Mr. M. J. Petty suggesting "salyrgan" for removing superfluous fluid. Has anyone tried the latter drug for the former object? I have recently had a patient whose mountainous breasts literally poured milk.

Heparin and Thrombosis

Mr. J. E. R. McDONAGH (London, W.) writes: Heparinized tubes are convenient for collecting blood for examination which has to be sent by post. In specimens collected in this way the percentage of the blood sugar cannot be estimated; if examined soon after the blood is withdrawn the blood sugar may be either slightly raised or lowered. The sedimentation rate is always increased and so are the refractive index, the viscosity, the viscosity-refractive index, and the viscosity-protein index. The percentage of the blood urea and the protein are as a rule increased, and it is only rarely that they are unaltered or slightly lowered. The picture obtained with the dark-ground condenser shows more precipitated colloid particles and a large number of crenated and contracted red blood corpuscles. Heparin appears to have the same action as sodium poly-anethol sulphate ("liquoid"). In the terminology I am in the habit of employing, I believe that the first action of these preparations is to dehydrate the colloid particles in the blood and the subsequent action is to hydrate them. I hold the prevention of coagulation to be due to the exhibition of the latter chemico-physical change. Thrombosis when it occurs in a healthy vein I regard as due to gelation, which is one of the phenomena produced in dehydration. It is one which in my experience is best remedied by intramuscular injections of Sum 468 in doses of 0.001 to 0.002 gramme. Larger doses may be employed when it is desired to reduce the number of injections: eight or more to one or two, but in this case the injections need to be made intravenously. Thrombosis in an artery falls into a different category and requires different treatment, because it is secondary to disease of the vessel wall.

A Delivery Towel for Midwifery

Dr. R. E. M. TAUNTON (Hanwell, W.) writes: In reply to Mr. Ernest B. Hinde's note in the *Journal* of October 29 (p. 924) on the use of a special towel with a pocket, a sterile towel is not always available in general practice. I have found with practice that I can use my left elbow for pressure on the fundus just as well as my left hand, and so keep the left hand sterile. I have used this method for many years.

Diverticulum of Duodenum.—Wheeler has analysed 2,000 consecutive cases examined radiologically and has found 142 (7.1 per cent.) in which duodenal diverticula were present. He suggests that these diverticula should be divided into, primary, those which have no obvious cause and are found in the second, third, and fourth parts of the duodenum, and secondary, which are always the result of chronic duodenal ulceration and occur only in the first part of the duodenum. Like Odgers, the author believes that the majority of these diverticula do not give rise to any symptoms and that their significance has probably been exaggerated.

Demonstration of Tubercle Bacilli.—This study comes from the bacteriological laboratory of the communal hospital in Essen, and it deals with Hagemann's microscopical fluorescent test for tubercle bacilli. A comparison was made with 1,424 specimens subjected to this test and to Ziehl-Neelsen staining. The Hagemann test invariably proved much superior to the Ziehl-Neelsen staining technique. The demonstration of even isolated tubercle bacilli was greatly facilitated by Hagemann's procedure, which did not in a single case give a negative result when the findings by Ziehl-Neelsen staining were positive.

Tuberculosis in India.—For India as a whole tuberculosis is a very serious disease, because of its tendency to show itself in an acute form. There is a general lack of immunity among Indians as a race. The drift of the population towards the cities is a dangerous factor in the situation.

BCG Vaccination.—The value of BCG in the prevention of tuberculosis has been definitely proved in many countries. It is effective when administered by the oral route. There is no proof that it may cause the onset of tuberculous meningitis.

Journal of the American Medical Association

Chicago vol. 111 September 10, 1938

 Human Requirements for Vitamin B G. Coagill—p. 1009
 Physical Therapy in Treatment of Fractures I. Dickson—p. 1010

Sulphanilamide and Serum in Scarlet Fever.—Sako and collaborators compared a series of 100 scarlet fever patients treated with sulphanilamide with 100 not so treated. The series were comparable in respect of age and of severity and duration of the disease before treatment. An initial dose of 0.05 gramme and a maintenance dose of 0.03 gramme per lb.

body weight was given in each twenty-four hours. Complications occurred in 8 per cent. (of which one was suppurative) of treated cases, as against 41 per cent. (of which nine were suppurative) of controls. Recovery from the acute toxæmic phase was the same in both series, and for this reason the authors conclude that massive intravenous serum therapy at the beginning of the disease combined with the administration of large doses of sulphanilamide throughout the whole period of the infection is the most efficacious method of treatment.

Estimation of Haemoglobin in Undiluted Blood using Lovibond Comparison. G. A. Harrison.—p. 621.

Administration of Hormones.—Deanesly and Parkes have investigated experimentally the effectiveness of crystalline gonadal hormones when administered by the subcutaneous implantation of solid tablets of the pure substance. The technique is particularly useful when a long-continued steady effect is required, as, for example, in the depression of the gonad-stimulating and growth-promoting activity of the pituitary by oestrogens, and in the masculinization of the female by androgens. Treatment of very long duration following one administration of hormone will apparently be possible by this method of implantation.

Acute Bowel Obstruction: Recognition and Management. O. H. Wanzel.—p. 340.
Clinical Evaluation of Some Non-volatile Anaesthetic Drugs. L. F. Siew.—p. 349.

Appendicitis in Adults.—Walker reviews 5,371 cases of acute appendicitis; the incidence of generalized peritonitis was 2 per cent. Patients moderately ill with generalized peritonitis can be operated on immediately with a comparatively low mortality. Those seriously ill, if treated in this manner, show a high death rate. Thus seventy-seven cases of generalized peritonitis treated by immediate operation gave a mortality of 42 per cent. On the other hand, a group of thirty cases treated for toxæmia and with delayed operation showed a mortality of 13 per cent. Delayed operation has, of course, no place in the treatment of the acute unruptured appendix.

*Benzedrine with Belladonna in Treatment of Chronic Encephalitis Lethargica. B. Disertori—p 1768

Chronic Encephalitis Lethargica.—According to Disertori benzedrine cannot replace belladonna in the treatment of chronic encephalitis lethargica, but it is a useful auxiliary to belladonna treatment. In combination with belladonna in

large doses benzedrine led to notable improvement in two-thirds of cases, it had little effect on rigidity and tremor, but improved oedogenic crises, statorrhoea, and subjective symptoms.

Presse Médicale

Paris vol 45 September 7, 1938

*New Case of Haemolytic Anaemia with Haemoglobinuria and Haemoglobinemia. M. Bille, P. Hildbrand, and R. Gaube—p 1329
Lactulose Tolerance Test for Hepatic Insufficiency. F. Moreau, R. Riviere, R. Guyot, and A. Bermond—p 1331

Haemolytic Anaemia.—The authors describe a case of this unusual form of anaemia. The patient showed an anaemia of the haemolytic type but without fragility of the corpuscles, with haemoglobinuria and haemosiderinuria. The condition does not appear to be improved by any known form of treatment, including splenectomy.

Paris vol 45 September 10, 1938

*Prevention and Abortive Treatment of Post-operative Phlebitis. A. Chabrier—p 1345
*New Method at Classification of Streptococci. Its Clinical Significance. P. Hauduroy—p 1346

Post-operative Phlebitis.—The author describes the treatment he has used for the last ten years in over 2,000 abdominal operations. The prophylactic treatment consists essentially in allowing the patient to get up not later than forty-eight hours after the operation, under suitable conditions of observation, in order to detect the first signs of trouble. The "abortive treatment" comprises the following measures: encouraging the patient to get up and walk as much as possible; raising the foot of the bed in order to help the return circulation when the patient is lying down; and the administration of cardiac tonics and anticoagulants.

Streptococci.—After showing the unsatisfactory character of classifications used up to the present time, the author pleads for the wider adoption of Lancefield and Hare's classification, which is based on the antigenic properties of the organisms.

Paris vol 45 September 12, 1938

*Kidney in Cirrhosis. A. Tresselt and A. Vazay—p 1361
*Classification and Pathogenesis of Endemic and Sporadic Thyroidism. D. Danielopolu with Stoichita Cosma, A. Dercu, M. Dercu, I. Emanuel, N. B. Nestoresco, D. Nicolae, N. Radulesco, I. Rege, I. Tilica, and V. Vatu—p 1365

Kidney in Cirrhosis.—The authors, as a result of the detailed investigation of the metabolism of salts, creatinine, and water in their cases, come to the conclusion that the kidney does not show any constant changes capable of explaining any particular syndrome or syndrome, and that the mechanism of diuresis is much more complex than is usually thought.

Thyroidism.—The authors have managed to collect between them 38,657 observations relating to cases of endemic or sporadic thyroidism. As a result of their joint investigations they have adopted the following physio-pathological classification: (1) "normothyroidism"—that is, simple or colloid goitre; (2) hyperthyroidism—that is, all syndromes due to "thyro-vegetative hypertonia", for example, Graves's disease; (3) hypothyroidism (thyro-vegetative hypotonia), including cretinism and myxoedema; and (4) "paragoitrous" conditions, such as "thyroid idioey", thyroid deafness and dumbness, etc. As will be seen, the basis for this classification is their conviction that the thyroid has an important vegetative function in addition to its morphogenetic and metabolic functions. This thesis is admirably worked out in a diagram showing the relation of the thyroid to the endocrines and central and vegetative nervous systems.

Paris vol 45 September 17, 1938

*Influenza. General Review of Anti-influenza Serum Therapy. A. Bectere—p 1385
*New Method for Treatment of Cutaneous Leishmaniasis (Oriental Sore). E. Flaher—p 1388

Influenza.—The author reviews the history of serum therapy since it was first tried in cases of influenza in 1918 by McGuire and Redden in the form of human convalescent serum, and later by Laidlaw, Smith, and Andrews with serum prepared from immunized horses. Bédère goes on to give an account of the latest work carried out in France by Dujarrie de la Rivière, Chevé, and himself. They are at present trying to produce a serum which will be efficacious not only against the influenza virus but also against Pfeiffer's bacillus, which would appear to be the cause of the dangerous pulmonary complications in this condition.

Cutaneous Leishmaniasis.—Professor Flarer, after reviewing the various treatments which have been used up to the present for leishmaniasis (including various forms of antimony, surgery, electrocoagulation, x rays, and fadium) and deploring the usual unsatisfactory results of treatment of the cutaneous form of the disease, states that he has treated fourteen such cases with atebirin with uniformly successful results.

- Does Fowl Paralysis resemble Poliomyelitis? E. Frauchiger and E. Bourgeois.—p. 1057.

Clinical Features of Cardiac Infarction.—The comparative frequency of "atypical cases" without agonizing pain is emphasized—it is over 40 per cent. according to recent Basle records. In such cases a feeling of constriction in the chest and marked weakness of the peripheral circulation with tachycardia are early evident. An increase of temperature and a raised leucocyte count and sedimentation rate are usually noted. Other secondary symptoms and the electrocardiographic signs are reviewed.

- Circulatory Problems in Peritonitis (Eng.) P. Windfeld.—p. 293.
- Fracture of Mandible with Bilateral Onward Dislocation (Ger.) P. Einton.—p. 304.

Fibrous Pericarditis.—These two articles stress the necessity for close collaboration between physician and surgeon in the diagnosis and treatment of fibrous pericarditis. Tengwall has operated on seven cases for this condition, and reports four successes. One patient died immediately after the operation; two others died two and six months after operation respectively. Extensive lime deposits in the pericardium and co-existent organic cardiac disease influence the prognosis adversely.

Radical Treatment of Rectal Carcinoma.—The author has collected nearly all the cases of carcinoma of the rectum

which occurred in Denmark between 1931 and 1935. Only 27.2 per cent. of all cases (1,444) were subjected to radical operations—that is, abdomino-perineal and perineo-sacral resections. The primary mortality of one-stage abdomino-perineal resections was 70.6 per cent., and the same operation carried out in two stages had a 60.6 per cent. mortality. Eiken recommends the two-stage sacral extirpation as the method of choice for all but very high growths.

Injection Therapy of Varices.—This is a very detailed investigation into the causes of relapse after the injection of varicose veins. The author comes to the conclusion that simple injection treatment is sufficient if only the veins of the leg are affected. Should the condition have spread to the thigh, ligation and excision of a section of the great saphenous vein should be combined with the injection treatment.

Milk Supplements.—Radiographs of the wrists and hands of 108 children were taken at the beginning and end of a calendar year and the progress in osseous development, as indicated by changes in the Carter ossification ratio, was noted. One-third of the children were kept on the usual institutional diet; one-third were given a pint equivalent of evaporated milk; and the remaining third received an equal amount of irradiated evaporated milk. The groups given the supplements showed greater progress than the control group, and the differences were significant and all tended in the same direction. There was, however, no significant difference in the two groups receiving milk supplements. The subjects of this experiment comprised all the residents in an institution caring for approximately 150 children of ages ranging from 1 to 15 years. The authors conclude that the daily addition of the constituents of a pint of milk proved "a factor of safety in a rather mediocre institutional diet."

Vitamin C Requirements.—In Detroit 427 infants were studied during the first year of life. About 10 mg. of vitamin C was made available to each infant daily by giving supplements of powdered lemon juice. Each infant was examined monthly or oftener. From their findings the authors conclude that "the condition which has usually been considered latent scurvy is actually definite mild scurvy." During the course of the study according to the criteria of Park and others twenty-one infants had mild scurvy.

Tuberculin Protein and Polysaccharide Molecules.—This is a summary of the results of an intensive study made by Florence Siebert (in collaboration with two Swedish workers)

into the chemical structure of the group of substances with tuberculin activity and the variation in their biological effects. The work was carried out in the laboratories of Professor Svédberg, director of the Institute of Physical Chemistry, Uppsala, Sweden. Siebert found that "purified protein derivative" itself was not perfectly pure, but contained substances with large and small molecular weights in addition to the main bulk of the product, which possessed a molecular weight of 16,000.

Incubation Period of Rabies in Dog. I. Dodaro. — p. 193.

Reinforcement Phenomenon in Chemotherapy. I. L. Krutshchinski. — p. 205.

Lesions produced by Dead Tubercle Bacilli.—Rist has confirmed the observations of several other authors on the effects produced by dead tubercle bacilli suspended in hard or liquid paraffin, olive oil, or vaseline. Whereas dead bacilli in saline produce only a local lesion when injected subcutaneously, their effect when suspended in any of these oily bases is to cause not only a more extensive local reaction but also distant lesions in lymph glands and in the lungs, to which particles of the substance containing the tubercle bacilli are carried. Such animals also develop marked tuberculin sensitivity. Immunizing effect is known to vary with the manner of administration (diphtheria toxoid, for example, has little immunizing power when given intravenously), and it is suggested that the greatly enhanced action of dead tubercle bacilli protected against rapid destruction by suspension in oil may serve as a model for more efficient methods of active immunization.

Hypercholesterolaemia.—A high fat diet, when it does not cause too frequent vomiting, will usually produce a moderate hypercholesterolaemia in dogs, and this can be markedly accentuated by also giving lecithin. The dog may therefore prove a suitable animal for studying the possible relationship between hypercholesterolaemia and atheroma.

*Tetralateral and Fasciculation in Voluntary Muscle. D. Dennis-Brown and J. B. Pennybacker. — p. 311.

Pick's Disease.—The literature on this disease is briefly reviewed and a case is described clinically and pathologically. The authors conclude that the condition is a specific

type of dementia. Clinically there are psychical inertia, stereotypy, and disturbances of general and ethical judgment, and a special feature is that memory is not lost but cannot be used in the formation of new ideational material. Pathologically there is atrophy of the frontal, temporal, and insular areas, so that the encephalogram is useful in diagnosis. The degenerating nerve cells show argentophil bodies, and there is intense gliosis.

Tonic Foot Response.—This phenomenon consists in a flexion and adduction movement of the toes associated with a curving of the foot elicited by a touch or pressure stimulus to the sole of the ball of the foot. It is a pathological phenomenon, and is considered one of the earliest signs of a lesion of the frontal lobe. Cases showing the sign are described and its explanation is discussed.

Fibrillation and Fasciculation in Muscle.—After a detailed review of physiological observations on muscular function the authors record the results of a clinical and electromyographic study of involuntary fibrillary twitching in muscle. The following phenomena are described: fine fibrillation in a muscle completely deprived of its nerve supply; the fasciculation of muscle in motor neurone disease; fascicular tremor observable in patients with wasting diseases; myokymia; post-paralytic facial contracture; and myoidema. The possible nature of these phenomena as revealed by the electromyographic findings in the muscle is discussed.

Experimental Hypertension.—Goldblatt's review of the experimental hypertension which may be induced by renal ischaemia is based on a survey of some 200 papers. Of particular interest is a tabular classification of the procedures undertaken from 1879 onwards in investigating experimentally the possible renal origin of hypertension. The author concludes: "All of the investigations that have been directed toward the study of the pathogenesis of this type of experimental hypertension have yielded results that indicate the existence of a humoral mechanism of renal origin that is

responsible for the vascular constriction and consequent increased peripheral resistance which produces the elevation of the blood pressure."

Acute *Micrococcus catarrhalis* Arthritis. W. M. Solomon and H. R. Tuckwell.—p. 1061.

Sciatic Pain of Unknown Origin.—For those cases of sciatica in which the aetiology is obscure the author has used perineural injections of 1 per cent. novocain with considerable success. This treatment may be combined with traction applied to the lower extremity, or low-back manipulation under general anaesthesia.

Osteogenic Sarcoma.—This paper deals with the results obtained at the Mayo Clinic during the years 1909 to 1934 in the treatment of cases of osteogenic sarcoma. A definite relationship can be established between the grade of malignancy as determined by the pathologist and the survival rate. Grade 1 cases had a five-year survival rate of 60 per cent., while only 11.1 per cent. of Grade 4 patients were alive after five years. Of 158 patients treated by any method, 23.4 per cent. lived for five years or more.

Backache.—A large series of patients suffering from low-back pain have been subjected to manipulative treatment without anaesthesia. Careful investigation of each case is necessary in order to eliminate gross lesions which would obviously constitute a contraindication to any manipulation. Cases of acute sprain and those of chronic trauma produced by faulty posture are greatly benefited by this treatment.

Dysentery Agglutinins.—Many specimens of serum obtained for the Wassermann test or from medical students in a district where dysentery is rare were examined for dysentery agglutinins. In no case were Shiga or Sonne suspensions agglutinated at a greater serum dilution than 1 in 20, but with Flexner suspensions more than half the specimens were positive up to 1 in 40 and about a fifth at 1 in 160. Similar results were obtained in a small series of tests with blood obtained from the umbilical cord at birth. There was no significant difference in the proportion of positive results between males and females. These findings make it appear doubtful whether the presence of agglutinins for *Bact. dysenteriae* Flexner is evidence of previous infection by this organism. Sonne suspensions are almost invariably agglutinated by ox and sheep blood, less often by blood from rabbits and guinea-pigs.

Sensitization in Convulsive States.—The presence of heterophile antibody was investigated in the blood of thirty-six insane epileptics by several techniques, the results of which are given in detail. These results do not appear conclusive, but, together with the fact that attacks seem to be pre-

cipitated by certain foods and that the antibody content of the blood is reduced after an attack, they are considered to indicate that sensitization to foreign animal protein plays a part in this disease.

Surgery of Human Ureter.—The author reviews the range of modern ureteral surgery, and describes the methods of approach for the various operations upon each section of the ureter; also briefly referred to are transurethral cystoscopic operations upon the ureter. The author warns against the too energetic use of ingenious contrivances for grasping ureteral stones and pulling them down into the bladder.

Recurrent Renal Lithiasis.—Higgins refers to the wide diversity of opinion in published reports on the frequency of recurrence of renal calculi. He reviews the factors found to be operative in his series of 100 cases: age, sex, race, site of recurrence, time of recurrence, concurrent infection, focal infection elsewhere in the body, and the significance of vitamin A deficiency. By the application of prophylactic measures, directed especially to the correction of any vitamin A deficiency, his recurrence rate has been reduced from 16.2 per cent. to 4.7 per cent.

Local Repair after Transurethral Prostatic Resection.—The process of healing following prostatic resection with the McCarthy resectoscope is described, as are subsequent changes in contour and structure. The author discusses also various factors in relation to the technique of the operation, occurrence of haemorrhage, and recurrence of bladder-neck obstruction, and the incidence of incontinence and post-operative infection.

Rheumatic Heart Disease in Students.—The results of an investigation embracing 104,163 students in eighty-six colleges and universities are collated and discussed, especially in relation to pulmonary tuberculosis. All forms of heart disease from valvular lesions to adherent pericardium were considered. The case rate among women students was higher than that among men—14.9 per 1,000 as against 9.5. In contradistinction to the adult type of pulmonary tuberculosis, the reported incidence of heart affections was lower in institutions with well-organized health services. Emphasis is laid upon the necessity for careful and individual examination, as there is no "mass method" of diagnosis comparable to tuberculin testing and screening as in tuberculosis. The problem is not confined to mere case-finding, but extends to correct evaluation of the physical signs, and involves ascertainment of the prognosis so far as it affects the career of the students in college and in after-life.

- Infectious Disease Returns: United States, Foreign, and Insular.—p. 1721.

Sewage Purification.—This is an elaborate discussion of the chemical, biological, and mathematical factors involved in sewage purification by activated sludge methods. A collection of postulates, axioms, and guide-rules in relation to efficient working of the process is given in the summary. The general result of the investigation goes to show that there is no fixed optimum of in-fed activated sludge for sewage plants in general, but each plant has its own characteristic. Upon the correct determination of this factor depends the efficiency of the installation.

Washington vol. 53 September 30, 1938

- Prevalence of Communicable Diseases in United States: August 14 to September 10, 1938.—p. 1733.
- *Motetted Inamel Survey of Bauxite, Arkansas, Ten Years after Change in Common Water Supply. H. I. Dean, I. S. McKay, and E. Elvove.—p. 1736.

- Infectious Disease Returns: United States, Foreign, and Insular.—p. 1739.

Water Supply and Fluorosis of Teeth.—The production of an unusually severe type of endemic fluorosis (mottled enamel) of the teeth at Bauxite, Arkansas, was arrested when a change was made from the former water supply, which contained a comparatively large amount of fluorides, to a new one with a low fluoride content. This is the second instance in the United States where a change from an otherwise satisfactory water supply has been made on account of its disastrous effect on the teeth of children, the other being at Oakley, Idaho. The article is accompanied by a dozen photographic plates illustrating the dentures of affected children.

- Infectious Disease Returns: United States, Foreign, and Insular.—p. 1801.

Concentration of Vitamin E.—A vitamin E concentrate, potent in doses of from 3 to 7.5 mg., has been prepared by the elimination of substances insoluble in methanol at dry ice temperature from the unsaponifiable fraction of wheat-germ oil. The technique of preparation and the method of assay are described.

- Radiotherapy of Chronic Tonsillitis. P. Hers.—p. 393.
- Radiotherapy of Sinusitis. J. Popp.—p. 399.

Radiotherapy of Generalized Affections.—The therapeutic value of "total" irradiation (panteleradiotherapy) in leukaemias, erythrocythaemia, and lymphogranulomatosis varies. So far the best results have been obtained in the leukaemias, particularly in the myeloid forms, and in erythrocythaemia. However, apart from the last affection, the results of total irradiation are not yet such as to justify the abandonment of the older methods of regional irradiation; on the other hand, total irradiation has proved successful in some cases in which regional irradiation had ceased to have any effect. The method is not without dangers, and individual sensitivity to total irradiation varies greatly.

- Problems in Surgery of Thyroid Gland. G. Crile.—p. 363.

Conization of Cervix.—A complete review is given of the technique and results of, and indications for conization of the cervix. It is considered that electrosurgical conization is the best method of treating stubborn chronic cervicitis in women past childbearing age. Particulars are given of the results obtained in a series of 899 cases.

Temporo-mandibular Ankylosis.—In this article a clinical study is presented of thirty-three cases of chronic ankylosis of the jaw. The aetiology and pathology are fully discussed and methods of treatment are described and fully illustrated. A detailed report is given of ten cases which present fair examples of the more unusual problems met with in this condition.

HORMONE TREATMENT

in imperfect descent of the testis

"The disadvantage of waiting for spontaneous descent in any except the retractile type is that if an anatomical abnormality be present, the diagnosis of which may deceive even the elect, spontaneous descent can never occur. Waiting until after puberty in the hope of spontaneous descent is in such a case an unnecessary and unjustifiable delay. Analysis of the results in the present series shows that if in cases of doubt a retained testis does not respond after six months of hormone treatment, it is highly probable that there is an anatomical abnormality."

Balanced nutrition for your patient

of any age

Farex is a blend of 3 cereals—wheat, oatmeal and maize. In addition to providing an adequate proportion of carbohydrate, it contains a special amount of protein. It is rich in minerals (including iron, calcium and phosphorus) . . . it has a naturally high content of vitamins A and D. Thus Farex provides nourishment and protective elements in an easily digestible form for infants, children, adolescents and adults, whether ill or well.

GLAXO LABORATORIES LIMITED, GREENFORD, MIDDLESEX

Farex is invaluable for WEANING, and it helps to make good the diet deficiencies that occur in CHILDREN, ADOLESCENTS, ADULTS and INVALIDS

ST. ANDREW'S HOSPITAL FOR MENTAL DISORDERS NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President, THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: THOMAS TENNIST, M.D. M.R.C.P., D.P.H., D.P.M.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 350 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

All the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf course, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

CRICHTON ROYAL, DUMFRIES for NERVOUS AND MENTAL DISORDERS

Cases of alcoholism and drug addiction are admitted.

This Hospital has every facility for complete investigation and treatment of the above conditions.

The Physiotherapy Department has separate units fully equipped for X-ray work, heliotherapy, short-wave therapy, electro-therapy, and hydrotherapy. There is a fully equipped Gymnasium and indoor Swimming Bath under qualified instructors. Facilities are provided for all indoor and outdoor recreation, including golf course, cricket, football and hockey grounds, lawn tennis and squash courts, croquet and bowling greens, and a Cinema.

The Hospital grounds, extending to nearly 1,000 acres, are situated in delightful country, and include an extensive farm (T.T. herd), gardens and orchards.

Private rooms, suites or villas are available, and special nurses can be provided. As the Hospital is well endowed terms are exceptionally moderate, e.g., First Department, 3 to 30 guineas per week; Second Department, 2 and 2½ guineas per week. Voluntary and certified patients are received. Medical Certificates given anywhere in the British Isles are valid for admission of patients. For prospectus, necessary forms, and further information apply to:

Physician Supt.: P. K. MCCOWAN, J.P., M.D., F.R.C.P., D.P.M., Barrister-at-Law. Tel.: Dumfries 1119.

THE INCORPORATED LIVERPOOL SCHOOL OF TROPICAL MEDICINE (University of Liverpool).

Applications are invited for the post of ASSISTANT LECTURER AND DEMONSTRATOR in the Department of Parasitology at the above School.

Candidates should be graduates of a British or Colonial university, and must hold a medical qualification of a good degree in zoology. Initial salary £300-£400 according to the selected candidate's qualifications.

Applications should be made not later than December 31st 1938, to the Secretary, School of Tropical Medicine, Pembroke Place, Liverpool, 3, from whom further particulars may be obtained.

COUNTY BOROUGH OF BOURNEMOUTH. ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER (Male)

Applications for the above are invited from duly qualified Medical Practitioners who should be aged not under 20 years of age and hold a Diploma in Public Health.

The successful candidate may be required to undertake public health work, but special experience of infectious diseases, including immunization, is desirable.

Good salary and holidays with or without provision at the hospital for infectious diseases, and for those a deduction of £100 per annum will be made from the salary, which will commence at £450 and rise by annual increments of £25 to a maximum of £725, less 5 per cent deduction for superannuation purposes.

Application forms can be obtained from the Medical Officer of Health, Town Hall, Bournemouth, to whom they must be returned, with copies of three recent testimonials, not later than the first day of December 1938.

Candidates of either kind will be a disqualification. Town Hall, HERBERT ASHLING, Town Clerk. November 15th 1938.

POST-GRADUATE COURSE IN VENEREAL DISEASES

LONDON COUNTY COUNCIL (WHITECHAPEL) CLINIC, TURNER STREET, E.1 (ADJOINING THE LONDON HOSPITAL).

A THREE MONTHS' COURSE OF INSTRUCTION IN MODERN METHODS in the DIAGNOSIS and TREATMENT OF VENEREAL DISEASES will be given by Lieut.-Colonel E. T. BURKE, D.S.O., the Director of the Clinic, during January, February and March, 1939. Attendance at this Course will qualify, subject to the other conditions in the Regulations of the Ministry of Health, for the Certificate enabling the possessor to hold the position of a Venereal Diseases Officer under the Council of a County or County Borough. The Course will consist of twenty-five systematic lectures, accompanied by lantern demonstrations, on Mondays and Thursdays at 2.30 p.m., beginning on 9th January and ending on 30th March, 1939. Every Wednesday at 2 p.m. cases will be demonstrated. Those taking the Course will also attend the practice of the Clinic in order to obtain tuition in intravenous injections, etc. During the three months 130 hours of attendance must be put in.

Those intending to take the Course must send their names to the Director on or before 20th December, 1938. Fee: £10 10s.

NOTICE OF ELECTION. MIDWIVES (IRELAND) ACT, 1918

1. Notice is hereby given, pursuant to the Midwives (Ireland) Act, 1918, as amended and adapted by the Central Midwives Board Order, 1923, and the Regulations under the said Act, that the Returning Officer will, at the Offices of the Board, 33, St. Stephen's Green, Dublin, on Friday, 16th day of December now next ensuing, between the hours of 11 a.m. and 1 p.m., proceed to the nomination, and, if there is no opposition to the election of FOUR MEMBERS, of the Central Midwives Board.

Every registered medical practitioner is qualified to be nominated as a candidate.

Each candidate must be nominated by a separate nomination paper.

Every registered medical practitioner resident in Eire is entitled to take part in nominating four candidates, but no more.

Every nomination paper must state the names, address, and qualification or qualifications of the candidate nominated; it must be signed by not less than six registered medical practitioners resident in Eire, as nominating such candidate, and the address and registered qualification or qualifications of each medical practitioner so signing must be appended to his signature.

Every nomination paper must contain a declaration in writing, signed by the person nominated, acknowledging that such person consents to be nominated.

2. Forms of nomination paper may be obtained at the Central Midwives Board Offices, 33, St. Stephen's Green, Dublin, between the hours of 11 a.m. and 1 p.m. on any day (not being a Sunday or public holiday) before the said 16th day of December, 1938.

Any application for a nomination paper is to be sent by post must be accompanied by a prepaid addressed envelope.

Every nomination paper must be delivered to the Returning Officer by post or otherwise, either at the place above appointed for the purpose between the hours of 11 a.m. and 1 p.m. on the 16th day of December, or at any place at which the Returning Officer may be found at any time on any day before the said 16th day of December, 1938.

In the event of the election being contested, voting papers will be issued to the persons entitled to vote thereat as soon as practicable after the said 16th day of December, and the day for the counting of the votes will be the 18th day of January, 1939.

Votes cast by voting papers received by the Returning Officer on or after the said 18th day of January will not be counted.

(Signed) EDWARD COEY BIGGER, Returning Officer.

LONDON COUNTY COUNCIL

Applications invited from Medical Practitioners of at least one year's standing to undesignated positions. Candidates must have held resident appointment in a general hospital for at least six months. Married quarters not available.

LONDON COUNTY COUNCIL

Applications invited from registered medical practitioners of at least one year's standing, resident in the neighbourhood, for appointment as VISITING MEDICAL OFFICER (part-time) at Princess Mary's Convalescent Home, Maryvale, S.W.15, a year.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health, Staff Division, 2, County Hall, S.W.1, returnable by December 5th.

Canvassing disqualified.

ROYAL NAVAL MEDICAL SERVICE

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry at the end of March, 1939.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years, which if desired is usually extended to five years at the discretion of the Admiralty.

Officers who leave the Service at the end of the initial period of three years will be eligible for a gratuity of £400, and those who leave at the end of five years for a gratuity of £1,000.

At the end of five years' Short Service, permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Full opportunities exist for transfer to the permanent list. Marriage Allowance is paid under the same conditions as for other Naval Officers.

Opportunities are available for officers on the permanent list for postgraduate study, to specialise, to take higher examinations, and to obtain further qualifications.

Copies of the regulations for entry and conditions of service, including rates of pay, allowances and retired pay, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W.1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1939.

BIRMINGHAM POSTGRADUATE MEDICAL SCHOOL

There are three vacancies for HOUSE SURGEONS in the SURGICAL UNIT, British Postgraduate Medical School, Hammersmith Hospital. The appointments are for six months and are not renewable. Salary £105 per annum, with board, residence, and laundry. Duties to commence on January 1st, 1939.

Duties are mainly in General Surgery, but one appointment is to the Department of Traumatic and Orthopaedic Surgery. Applicants must have held a previous House appointment.

Applications with copies of testimonials, should be sent to the Dean, British Postgraduate Medical School, Duane Road, Shepherd's Bush, London, W.12, to arrive not later than the first post on Monday, December 12th 1938.

COUNTY COUNCIL OF DURHAM.

DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £600 per annum, rising by annual increments of £25 to £700 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered medical practitioner under the age of 50 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.

(2) He should have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(i) have had at least three years' experience in the practice of his profession; or

(ii) have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a hospital as Resident Medical Officer in charge of beds occupied by general medical or surgical cases; and

(iii) have received special training for a period of not less than six months in the diagnosis and treatment of tuberculosis.

(3) He will be attached to the County Health Department and will, subject to the direction of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

(4) He will be required to reside in his dispensary area, or such other area as required by the Council.

(5) He must be prepared, if called upon, to act as locum tenens to other members of the medical staff of the County Medical Officer.

(6) The holding of a Diploma in Public Health will be deemed an additional qualification for the post.

The candidate appointed will be required to pass the County Council's medical examination and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," and accompanied by copies of not more than three recent testimonials, must be addressed to the County Medical Officer, Shire Hall, Durham, and must be received by him not later than first post on Monday, December 5th, 1938.

J. K. HOPE,

Clerk of the County Council
 Shire Hall, Durham,
 November 14th, 1938.

COUNTY BOROUGH OF ROTHERHAM.

MEDICAL SERVICES COMMITTEE.

JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER (Male).

ALMA ROAD HOSPITAL.

Applications are invited for the post of Junior Assistant Resident Medical Officer at the Alma Road Hospital, Rotherham, at a salary of £180 per annum, together with the usual emoluments. The appointment will be for a period not exceeding twelve months, determinable by one month's notice on either side.

The appointment is subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

The hospital is a general training school for nurses and is a recognized school for the training of midwives. The medical staff is composed of visiting consultants, a medical superintendent, and four resident medical officers.

The person appointed will be required to act under the general direction of the Medical Superintendent.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Rotherham, and must be returned to the undersigned endorsed "Junior Assistant Resident Medical Officer" not later than noon on December 7th, 1938.

Municipal Offices, CHAS. L. DES FORGES,
 Rotherham. Town Clerk.

AYR COUNTY COUNCIL.

HAEMATOLOGICAL TECHNICIAN.

Applications are invited from experienced LABORATORY TECHNICIANS for the above post. The person appointed will be required to work under the County-Obstetrician, and the duties will consist in routine haemoglobin investigations and blood counts as required upon all patients attending the County Ante-natal Clinics and Maternity Hospitals. Salary will be at the rate of £240 per annum, subject to deduction for superannuation.

Applications, stating age, sex, experience, and present appointment, along with copies of three recent testimonials, to be submitted to the Medical Officer of Health County Buildings, Ayr, before December 15th, 1938.

LEICESTERSHIRE COUNTY COUNCIL

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND DISTRICT MEDICAL OFFICER OF HEALTH.

Applications are invited for the joint whole-time appointment of an Assistant County Medical Officer of Health for the Administrative County of Leicester and Medical Officer of Health for the Rural District of Barrow-upon-Soar in the said County at a salary of £800 per annum, with a travelling allowance of £140 per annum. Office accommodation and clerical assistance will be provided by arrangements to be agreed upon by the appointing Authorities. The estimated total population of the Sanitary District is 38,340, the acreage of the area being 54,804.

Applicants, who should not be over forty-five years of age, must be duly qualified and registered male medical practitioners with experience in Public Health duties and must hold the Diploma in Public Health or its equivalent. The Officer appointed will be required to reside at such place in or adjacent to the Sanitary District as shall be approved. As regards the duties of an Assistant County Medical Officer of Health the Officer will act under the general control of the County Medical Officer of Health and will be required to perform such duties as may from time to time be prescribed. As regards his duties as District Medical Officer of Health the Officer will be subject to the sole control and direction of the Local Sanitary Authority.

The joint appointment is subject to the approval of the Minister of Health and the Board of Education and also, so far as the Office of District Medical Officer is concerned, to the provision of the Sanitary Officers (Outside London) Regulations, 1935. The joint appointment will be one under the Local Government Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination. The joint appointment will be determinable by three months' written notice on either side, subject so far as the Office of the District Medical Officer of Health is concerned to the consent of the Minister of Health.

Forms of application, together with a list of duties, may be obtained from the undersigned and, accompanied by copies of not more than three recent testimonials, should be returned to him not later than December 13th, 1938.

Canvassing, directly or indirectly, will be deemed a disqualification.

County Offices, LUCAS E. RUMSEY,
 Grey Friars, Clerk of the County Council
 Leicester, November 21st, 1938.

SURREY COUNTY COUNCIL

PUBLIC HEALTH DEPARTMENT.

KINGSTON COUNTY HOSPITAL (305 Beds)

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from registered Medical Practitioners for the appointment, which will be vacant in January, 1939, of Resident Assistant Medical Officer at the Kingston County Hospital.

The Medical Officer appointed must have had postgraduate hospital experience in the administration of Anaesthetics as his duties will be largely those of Anaesthetist.

The appointment is for a period of six months, renewable for a further period of six months, and the salary is at the rate of £250 per annum, together with full residential emoluments valued at £125 per annum.

Applications, stating age, qualifications, and experience, and enclosing copies of not more than three recent testimonials, should be addressed to the Medical Superintendent, Kingston County Hospital, Wolverton Avenue, Kingston-upon-Thames, so as to be received not later than December 3rd, 1938.

County Hall, DUDLEY AUKLAND,
 Kingston-upon-Thames, Clerk of the Council
 November 14th, 1938.

HEBBURN URBAN DISTRICT COUNCIL

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Urban District Council invite applications from fully qualified Medical Practitioners for the whole-time appointment as Medical Officer of Health and School Medical Officer, at a total exclusive annual salary of £800. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The successful applicant will be required to devote the whole of his time to the duties of the appointment, and will not be allowed to engage in private practice.

Further particulars, together with a form of application, may be obtained from the undersigned.

Applications, accompanied by copies of not more than three recent testimonials, endorsed "Medical Officer of Health," must reach the undersigned not later than November 30th, 1938.

Canvassing the Members of the Council in any form will be a disqualification.

Council Offices, ERNEST FOXALL,
 Hebburn, Co. Durham, Clerk of the Council.
 November 15th, 1938

COUNTY COUNCIL OF DURHAM ASSISTANT WELFARE MEDICAL OFFICER

The County Health Committee invite applications for an Assistant Welfare Medical Officer (woman) at a commensurate salary of £400 per annum to rise by annual increments of £25 to £500 per annum. Travelling allowance will be paid by the County Council in accordance with a scale to be approved from time to time.

The appointment will be held subject to three calendar months' notice on either side and to the following conditions:

(1) The officer appointed must be a registered medical practitioner between the ages of 25 and 45 years, must devote the whole of her time to the duties of the office, and must not engage in private practice.

(2) She should either have had a previous appointment as Medical Officer of an antenatal clinic, with the approval of the Minister of Health, or have had at least three years' experience in the practice of her profession as medical or dental officer of a public authority, and antenatal work. The holder of a Diploma in Public Health will be deemed an additional qualification for the post.

(3) She will be subject to the directions of the County Medical Officer of Health.

(4) She will be required to reside in Durham City, or such other place as required by the Council.

(5) She must be prepared to undertake any duties in connection with the Maternity and Child Welfare Services of the County Council, including attendance at Birth Control Clinics.

(6) She must be prepared, if called upon, to act as locum tenens to other members of the medical staff of the County Medical Officer of Health.

(7) The appointment will terminate on marriage.

(8) The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications, endorsed "Assistant Welfare Medical Officer," with copies of not more than three recent testimonials, must be addressed to the County Medical Officer of Health, Shire Hall, Durham, and must be received by him not later than Saturday, December 10th, 1938.

K. HOPE, Clerk of the County Council
November 21st, 1938

COUNTY COUNCIL OF DURHAM DEPUTY COUNTY MEDICAL OFFICER OF HEALTH

The County Health Committee invite applications for the appointment of a Deputy County Medical Officer of Health at a salary of £960 per annum. Reasonable travelling and out-of-pocket expenses will be paid by the County Council.

Applicants must be duly registered medical practitioners, holding a degree or diploma in Public Health, and the gentleman appointed will be required to devote the whole of his time to the duties of the office and to reside in the City of Durham or other approved centre. The appointment will be held subject to three calendar months' notice on either side.

He will be expected to undertake any duties required of him by the Council bearing on the health and medical services of the County, and will act under the administrative control of, and be responsible to, the County Medical Officer of Health for his duties.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and to a medical examination as required by the Council for the purposes of the Act, and the statutory contributions to the Superannuation Fund under that Act will be deducted from the salary.

Applications, marked "Deputy County Medical Officer of Health," together with copies of not more than three recent testimonials, must be sent to the County Medical Officer of Health, Shire Hall, Durham, not later than Saturday, December 10th, 1938.

J. K. HOPE, Clerk of the County Council
November 21st, 1938

CHELSEA HOSPITAL FOR WOMEN Arthur Street, S.W.3.

There is a vacancy for a REGISTRAR AND RADIUM OFFICER (Gynaecological). Candidates must be Graduates in Medicine of a recognized university, or Fellows or Members of one of the Colleges of Physicians of London, Edinburgh, Ireland, or Fellows of one of the Colleges of Surgeons of England, Edinburgh, or Ireland. They must be registered under the Medical Act and engaged in consulting practice only. There is an honorarium of £75 per annum.

Applications are invited for the above post and must be sent to the undersigned, accompanied by copies of three testimonials, not later than Wednesday, December 7th.

GEORGE W. COOLING, Secretary.

WEST RIDING OF YORKSHIRE MENTAL HOSPITALS BOARD

APPOINTMENT OF MEDICAL SUPERINTENDENT

WADSWORTH MENTAL HOSPITAL near Sheffield

The West Riding of Yorkshire Mental Hospitals Board invite applications from duly registered medical practitioners for the appointment of a Medical Superintendent in their service at the Wadsworth Mental Hospital near Sheffield.

Candidates must have had previous experience as the Medical Superintendent or a Senior Medical Officer at a Mental Hospital. A special consideration will be given to candidates holding Membership of the Royal College of Physicians or a degree of a British University and who possess the Diploma in Psychological Medicine.

The person appointed will be required to devote his whole time to the duties of the office and to act in conformity with the provisions of the Lunacy and Mental Treatment Acts, and the general rules and regulations of the West Riding of Yorkshire Mental Hospitals Board.

The minimum and maximum salaries fixed for the position are £1,100 and £1,400. The appointment is for five years. The commensurate salary to be paid will, within this limit, be according to qualifications, experience, and in accordance with the provisions of the Board.

The person appointed will be provided with an establishment which will be deemed to be valued, for superannuation purposes at the sum of £50 per annum. There are no other emoluments attached to the position. The salary and value of the establishment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Application must be made in a form which can be obtained together with any other particulars from the undersigned, to whom the completed form should be returned not later than December 10th, 1938.

Candidates in any form will be disqualified from Board Office. G. H. H. BARNES, Clerk of the Board
West Street, Wakefield
(P.O. Box No. 25)

CITY OF MANCHESTER

CRIMINAL HOSPITAL (154 Beds)
Underwritten under the Regulations for the F.R.C.S.I.

The Public Health Committee invites applications from registered medical practitioners for the post of RESIDENT ASSISTANT OBSTETRICAL OFFICER at the above-named hospital which will become vacant in mid-January, 1939.

The salary for the appointment is £250 per annum, with board, residence and laundry in addition, subject to the Manchester Corporation Council's order of service.

The appointment will be made in the first instance for a period of six months renewable for a further six months but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Town Hall, Manchester, 2, and applications for the post must be received by him not later than Monday, December 5th, 1938.

Town Hall, Manchester, 2 R. H. ADCOCK, Town Clerk

Applications are invited for the position of MEDICAL OFFICER in charge of WEEKLY ANAESTHETIC and POST-NATAL CLINIC. Wednesdays, 2 to 4 p.m.; £115. 6d. per session. Good experience essential.

Applications, with full particulars and three testimonials, should be sent to the Hon. Secretary by December 9th, 1938.

(AMENDED ADVERTISEMENT.) COUNTY BOROUGH OF SOUTHEND-ON-SEA

SOUTHEND MUNICIPAL HOSPITAL

The Health Committee of the Town Council invite applications for the following appointment at their Municipal Hospital situated at Rockford, Essex. The Hospital at present comprises 450 beds but considerable extensions are in course of erection. There is a staff of Visiting Consultants, and the Hospital is a recognised Training School for Nurses.

DEPUTY MEDICAL SUPERINTENDENT (RESIDENT)—Commensurate salary £500 per annum rising by annual increments of £25 to a maximum of £600 per annum together with full residential emoluments valued for superannuation purposes at £150 per annum. Candidates must hold a higher University Degree in Medicine or be a Member of the Royal College of Physicians, and must have had considerable general hospital experience, including administration.

SURGICAL OFFICER (NON-RESIDENT)—Commensurate salary £400 per annum rising by annual increments of £25 to a maximum of £500 per annum with a non-resident allowance of £150 per annum. Candidates must be Fellows of the Royal College of Surgeons, and must have had considerable experience in emergency surgery and the treatment of fractures.

Both appointments are designated posts under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidates will be required to pass a medical examination. Letters of application, together with further particulars of the appointments may be obtained from the Medical Officer of Health, Municipal Health Centre, Warner Square, Southend-on-Sea, and applications should be received by him not later than Monday, December 5th, 1938.

H. J. MORWOOD, Town Clerk
November 15th, 1938.

NORTHUMBERLAND COUNTY COUNCIL

ST GEORGE'S HOSPITAL, MORPETH

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL OFFICER

The Visiting Committee of the above-named Hospital invite applications from fully-qualified and registered medical practitioners for the above appointment. The successful candidate will be required to reside in the Hospital.

The commensurate salary will be £450 per annum together with the usual emoluments—i.e., furniture, attendance, board, laundry and attendance valued for superannuation purposes at £100 per annum. An increase of £25 per annum will be granted on completion of twelve months' satisfactory service, and a further annual increment of £25 to a maximum salary of £450 per annum. A further £50 will be paid in the event of the successful candidate holding the D.P.H.

The candidate appointed will be required to pass a medical examination and to contribute under the Asylum Officers' Superannuation Act, 1909.

Applications stating age (not over 45 years) and full particulars of qualifications, experience, and appointments held accompanied by copies of three recent testimonials should be enclosed in an envelope endorsed "Mental Hospital Assistant Medical Officer," and addressed to the undersigned, so as to be received not later than December 12th, 1938.

Candidates are requested to apply to the undersigned for particulars of the post and to forward before Friday, December 2nd, 1938, twelve copies of application with copies of three recent testimonials for the Managing Committee. It is also necessary to send a copy of application to each member of the Honorary Medical Staff (twenty-three).

JEAN R. MURRAY,

Secretary.

THE ELIZABETH GARRETT ANDERSON HOSPITAL,
Euston Road, N.W.1

Applications are invited from fully qualified medical women for the part-time post of **SURGICAL REGISTRAR**—non-resident—honorarium £100 per annum. Duties to commence January 1st, 1939.

Particulars of the post can be obtained from the undersigned, in whom applications, with copies of three recent testimonials, should be sent before December 2nd, 1938.

JEAN R. MURRAY,

Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN.
Hackney Road, London, E.2.
(160 Beds.)

RESIDENT MEDICAL OFFICER required on January 1st, 1939.

The appointment is made for six months, and may be extended for further periods of six months, but cannot be held for more than two years. The Resident Medical Staff consists of the Resident Medical Officer as above, two Casualty Officers, two House Physicians, and two House Surgeons.

Salary (inclusive of panel fees) £200 per annum, with board, residence, and laundry. Candidates must have held a responsible resident appointment at a recognized hospital.

Forms of application may be obtained from the undersigned, and must be completed and returned on or before December 6th, 1938.

CHARLES H. BESSELL,

November 14th, 1938 Secretary.

THE QUEEN'S HOSPITAL FOR CHILDREN,
Hackney Road, London, E.2.
(160 Beds.)

HOUSE PHYSICIAN required, January 1st, 1939.

Six months' appointment. Salary at the rate of £100 per year, with board, lodging, and laundry.

Applications must be made on forms to be obtained from the undersigned, and be sent in, with copies of not more than three testimonials, on or before December 6th, 1938.

CHARLES H. BESSELL,

November 14th, 1938 Secretary.

THE GORDON HOSPITAL
For Diseases of the Rectum and Colon.
Vauxhall Bridge Road, S.W.1.
(62 Beds, extending to 102 in the future.)

Applications are invited for the post of **RESIDENT SURGICAL OFFICER** at the above Hospital. The appointment is for a period of six months to June 30th, 1939. It is desired that the successful candidate should commence duty January 1st, 1939. Salary is at the rate of £150 per annum (plus £25 for the six months to cover all duties relating to private patients), together with board, residence, and laundry.

Applications, accompanied by copies of three recent testimonials, should reach the undersigned by December 1st, 1938, and envelopes should be endorsed R.S.O.

E. S. FOLEY,

Secretary.

THE HOSPITAL FOR WOMEN,
Soho Square, W.1.

Applications are invited for the posts of **HONORARY CLINICAL ASSISTANTS TO THE SURGEONS IN CHARGE OF OUT-PATIENTS**. The appointments will be for attendance at one or two out-patient sessions per week for a period of six months, commencing January 1st, 1939. Sessions are held at 1.45 every week-day except Saturday.

Applications must reach the undersigned by Monday, December 12th, 1938.

J. P. HEMING,

Secretary.

THE PRINCESS BEATRICE HOSPITAL,
Earl's Court, London, S.W.5.
General Hospital (81 Beds)

RESIDENT SURGICAL OFFICER (male) required for a period of six months in the first place from January 1st, 1939, eligible for re-election. Salary at the rate of £200 per annum, with board, residence, and laundry (together with £25 to cover all duties during the six months relating to private patients). Previous resident experience and F.R.C.S. essential.

Applications, with copies of three recent testimonials, should be received by the Secretary not later than 9 a.m., Monday, December 5th, 1938.

THE PRINCESS BEATRICE HOSPITAL,
Earl's Court, London, S.W.5.
General Hospital (81 Beds)

Applications are invited for the appointment of **HONORARY ASSISTANT SURGEON** to the Ophthalmic Department of The Princess Beatrice Hospital. Candidates must be F.R.C.S. Eng. and engaged in consulting practice only.

Applications, together with copies of three recent testimonials, should be received by the Secretary by the first post on December 5th, 1938.

WOMEN'S HOSPITAL, CATHERINE STREET, LIVERPOOL.
(Gynaecological Hospital—120 Beds.)

HOUSE SURGEON wanted for six months from January 1st, 1939. Salary £100 per annum.

Applications and copies of testimonials to reach the Secretary of the Medical Board not later than December 8th, 1938.

THE HOSPITAL FOR SICK CHILDREN,
Great Ormond Street, London, W.C.1.

The post of **CLINICAL PATHOLOGIST** will be shortly vacant. Salary £750 per annum.

The appointment is whole-time and non-resident. Facilities, within certain limits, will be given for private pathological practice.

The successful candidate will be required to take up his duties preferably on March 1st, 1939.

Candidates must be registered Medical Practitioners with special experience in bacteriology and clinical pathology.

Applications, accompanied by not more than three testimonials given specially for the purpose, must be delivered to the undersigned not later than noon on Monday, December 19th, 1938.

Candidates must be prepared to appear before the Joint Committee on Wednesday, December 21st, 1938, at 4.45 p.m.

Forms of application and details of the appointment are obtainable from the undersigned.

HERBERT F. RUTHERFORD,

November, 1938 Secretary.

WEST HAM HOSPITAL FOR NERVOUS AND MENTAL DISORDERS.
Goodmayes, Ilford, Essex.

Applications are invited for a Male **JUNIOR ASSISTANT MEDICAL OFFICER** at the above Hospital. Candidates must be unmarried.

The commencing salary is at the rate of £350 per annum, rising by annual increments of £25 to a maximum of £650 per annum, together with emoluments consisting of board, laundry, and attendance, valued for superannuation purposes at £150. The person appointed will also be paid, in addition to his salary, the sum of £50 per annum on obtaining the Diploma of Psychological Medicine.

The appointment is subject to six months' probation, and to the provisions of the Asylum Officers' Superannuation Act, 1909, Class 1, and to a satisfactory medical examination.

The Hospital is situated ten miles from London. Applications, stating age and experience accompanied by copies of three recent testimonials must reach the Medical Superintendent not later than December 12th, 1938.

WOOLWICH AND DISTRICT WAR MEMORIAL HOSPITAL.
Shooters Hill, London, S.E.18.
General Hospital (112 Beds)

The Board of Management invites applications from suitably qualified male candidates for appointment as **CASUALTY OFFICER** for six months from January 1st, 1939. The remuneration will be at the rate of £100 per annum, plus board, residence, and laundry. The candidate appointed will act as deputy for the Resident Surgical Officer, and consequent opportunities for major surgery.

The closing date for the receipt of applications (which should be made on the prescribed form obtainable from the undersigned) is Monday, December 12th, 1938, and short-listed candidates will be invited to meet the Appointments Committee (at the Hospital) on Thursday, December 15th, at 4.45 p.m.

R. S. G. HUTCHINGS,

Secretary.

THE SALVATION ARMY, THE MOTHERS' HOSPITAL,
Lower Clapton Road, Clapton, E.5

Applications are invited for the appointment of a **WOMAN VENEREAL DISEASES OFFICER** to the Mothers' Hospital. (Salary 416 guineas per annum.)

Details of the appointment may be obtained from the Secretary-Superintendent, to whom the application, with details of previous experience and three recent testimonials, should be sent by November 30th, 1938.

FRED HAMMOND, Secretary

VICTORIA HOSPITAL, BLACK POOL
(182 Beds.)

Minimum emolument £250 p.a. with board, residence, and laundry. Candidates must be male, single, and fully qualified and registered. Membership of the Royal College of Physicians and some knowledge of tropical medicine is desirable but not essential.

Applications, stating age, with copies of not more than three recent testimonials, to be sent on or before December 15th, 1938, to:

D. A. C. PRICE, Secretary
Hospital for Tropical Diseases,
25, Gordon Street, W.C.1

NATIONAL HOSPITAL, QUEEN SQUARE, W.C.1

RESEARCH FELLOWSHIP

By the generosity of a private donor a FULL-TIME RESEARCH FELLOWSHIP has been created for the investigation of DISORDERS OF THE MIND at the National Hospital, Queen Square, London, W.C.1.

The Fellowship will be open to graduates in science or medicine and is of the value of £100 per annum, tenable for one year in the first instance.

Applicants should state their previous experience and the method of investigations they propose to adopt.

Further particulars may be obtained from the Secretary, National Hospital, Queen Square, W.C.1, and applications should reach him by January 15th, 1939.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL

(Incorporated by Royal Charter)
High Holborn, W.C.1

Applications are invited for the office of ASSISTANT SURGEON. Two appointments will be made.

Candidates for this office must be Fellows of the Royal College of Surgeons of England, and in addition must have served the office of Clinical Assistant or House Surgeon at an ophthalmic hospital or ophthalmic department of a recognised general hospital for three years. They must also produce a certificate of age.

Applications, together with copies of three testimonials, should be forwarded on or before Wednesday, December 8th, 1938, to the Secretary from whom further particulars can be obtained.

DREADNOUGHT SEAMEN'S HOSPITAL

Greenwich, S.E.10

JUNIOR PATHOLOGIST, Desport Pathological Laboratory

The Committee of Management of the Seamen's Hospital Society invite applications for this post. The appointment in the first instance will be for one year at a salary of £400 per annum, but the elected candidate will be eligible for re-election for a second year.

Applications, stating age and experience, with copies of not more than three recent testimonials, to be sent in on or before Friday, December 9th to the undersigned.

DREADNOUGHT HOSPITAL, GREENWICH, S.E.10

(Seamen's Hospital Society)

One HOUSE PHYSICIAN and one HOUSE SURGEON required for six months from January 1st, 1939. Salary £100 per annum and a proportion of fees, with board, residence and laundry. Candidates must be male and single.

Applications, with copies of three testimonials, to be sent in on or before December 1st to the undersigned.

November 11th, 1938 I. A. LYON, Secretary

KING'S COLLEGE HOSPITAL

The Committee of Management invite applications for the post of ASSISTANT PHYSICIAN. Applications, with copies of three testimonials, should be sent before December 10th to the House Governor, King's College Hospital, Denmark Hill, S.E.5, from whom particulars of the duties may be obtained. Candidates must be Members or Fellows of the Royal College of Physicians of London.

HAMPSHIRE GENERAL HOSPITAL

Haverstock Hill, N.W.3

Applications are invited from single medical men for the post of HOUSE SURGEON for six months, vacant January 1st next. Salary £100 per annum.

Applications on the prescribed form, with copies of three testimonials, to be returned to the Secretary by December 10th.

QUEEN MARY'S HOSPITAL FOR THE EAST END, St. Dunstons, London, E.15.

Applications are invited from fully qualified and registered medical men (only) for the following posts:

| | Salary | Period |
|---------------------------|-----------|----------|
| 1 HOUSE SURGEON | £120 p.a. | 6 months |
| 1 HOUSE PHYSICIAN | £120 p.a. | 6 months |
| 1 OBSTETRIC HOUSE SURGEON | £120 p.a. | 3 months |
| 1 OUT-PATIENT OFFICER | £150 p.a. | 6 months |

The appointment will date from January 1st, 1939, and will be for six months except in the case of one House Physician, which will be for three months. In the case of the Obstetric House Surgeon, above referred to, the appointment will be for three months as Junior at £110 per annum and for three months as Senior at £130 per annum, six months in all.

The Hospital contains 219 beds including 50 for Maternity.

Candidates, who must be single, should send applications, accompanied by copies of testimonials to the undersigned, not later than Wednesday, November 10th, 1938.

RAPHAEL JACKSON, Major, Secretary

ROYAL MASONIC HOSPITAL

Ravenhill Park, W.6.

A post of RESIDENT MEDICAL OFFICER (male), preferably with M.R.C.P. qualification, will be vacant on January 1st, 1939. Salary at the rate of £300 per annum, with board, residence and laundry. The appointment is for twelve months. Candidates must be registered and must have held resident appointments in General Hospitals.

The Institution (145 beds at present, but to be increased) is primarily for raising patients of both sexes of moderate means usually unable to afford ordinary Nursing Home treatment, etc.

Applications, stating full particulars, to be sent on or before Monday, December 5th, 1938, to the Honorary Secretaries, from whom further information can be obtained.

ST. PAUL'S HOSPITAL FOR UROLOGICAL AND SKIN DISEASES

Trench Street, London W.C.2

Applications are invited for the post of male HOUSE SURGEON. Candidates must be qualified and registered. Salary £100 per annum, with board and residence. The appointment is for three months in the first instance, and the holder will later be eligible for the post of Resident Medical Officer. During his appointment as House Surgeon the duties involve work in the surgical wards and in the Out-patient Department.

Applications, with copies of recent testimonials to be submitted not later than December 15th. The successful candidate will be required to take up duty about the end of December.

November 23, 1938.

By Order of the Council.

G. C. ANDERSON, Secretary.

COUNTY MENTAL HOSPITAL, LANCASTER

Applications are invited for the post of ASSISTANT MEDICAL OFFICER (female). Candidates must be single and under 35 years of age. Commencing salary £550 per annum, rising to £600 after one year's satisfactory service, with further increases on promotion, subject to a deduction of 3 per cent. under the Asylum Officers' Superannuation Act, 1909. There are no emoluments.

The selected candidate will be required to live in the Hospital, and she will be provided with board, lodging, etc. for which a charge of £150 a year is made.

The possession of a Diploma in Psychological Medicine will entitle the officer to an additional £50 per annum.

Applications, giving full particulars, with testimonials (copies only), should be forwarded to the Medical Superintendent on or before November 30th, 1938.

CHILDREN'S HOSPITAL, NOTTINGHAM.

Applications are invited for the post of RESIDENT HOUSE SURGEON (woman). The salary will be at the rate of £150 per annum, with apartments, board and laundry. The appointment will be for six months, duties to commence on January 1st, 1939.

Applications, together with testimonials, stating age, qualifications and experience, to be sent to the Honorary Secretary, 1, King John's Chambers, Broadsmith Gate, Nottingham, on or before Tuesday, November 29th. Selected candidates will be required to attend at the Hospital for a personal interview.

COSHAM MEMORIAL HOSPITAL, KINGSWOOD, BRISTOL.

The Managing Body invite applications for the post of HONORARY ANAESTHETIST. Small honorarium paid. Applications to the Secretary.

ALEXANDRA HOSPITAL FOR CHILDREN WITH TUBERCULOSIS, SWANLEY, KENT

(100 Beds for Children with Bone and Joint Tuberculosis and other Orthopaedic Conditions.)

Applications are invited for the post of SECOND RESIDENT MEDICAL OFFICER at this hospital, which will become vacant in January next. Candidates for the appointment must be fully qualified, and should preferably hold a higher surgical qualification or be working for such higher qualification. The appointment is for six months, with eligibility for re-election. The salary will begin at the rate of £240 to £250 a year, according to qualifications and experience. Board and lodging are provided.

Applications, stating age and giving full particulars of qualifications and previous surgical experience, with copies of two testimonials, should be sent not later than December 14th to the undersigned at the London Office, 107, Southampton Row, W.C.1, from whom further particulars of the duties and conditions of the appointment can be obtained.

November, 1938.

STANLEY SMITH,
Secretary.

THE BOLTON ROYAL INFIRMARY, (318 beds, including 20 Auxiliary Hospitals.)

ASSISTANT PATHOLOGIST.

Applications are invited from qualified medical men or women for the above post. Post-graduate experience in the routine methods of a general hospital laboratory is essential.

The appointment is a whole-time one. Salary £600 per annum.

Further information may be obtained from the undersigned, to whom applications stating age, nationality and experience, and enclosing two copies of recent testimonials, should be sent not later than November 28th, 1938.

H. CORLESS,
Secretary.

ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury near Manchester (252 Beds.)

RESIDENT MEDICAL OFFICER

Applications are invited for the post of RESIDENT MEDICAL OFFICER. Salary £150 per annum. The appointment is for a period of six months, commencing January 1st, 1939. Candidates must be unmarried and duly registered. Previous hospital experience essential.

Applications, stating age, and accompanied by copies of not more than three recent testimonials, to be sent to the undersigned not later than Friday, December 2nd. Canvassing directly or indirectly is disallowed.

By Order,
H. HEARDMAN,
Secretary.

has been shown to possess **CONSPICUOUS ADVANTAGES** over other local anæsthetics

Percaine has become so firmly established within the last few years that there are over

2,000 PUBLISHED REFERENCES

to its pharmacological properties and uses in all fields of surgical practice.

TOXICITY in minimal effective concentrations less than that of either cocaine or procaine (1, 2).

DURATION of action greatly exceeds that of either cocaine or procaine (3, 4, 5, 6, 7, 8, 9, 10, 11, 12).

ONSET approximately as rapid as with cocaine or procaine (3, 4).

IRRITATION of the tissues and

DELAY in **HEALING** completely absent (3, 4, 13, 14, 15, 16, 17, 18, 19, 20, 21).

AFTER-PAIN abolished or materially reduced (3, 5, 14, 15, 16, 22, 23).

FALL IN BLOOD-PRESSURE in spinal anæsthesia considerably less than with procaine (20, 24, 25, 26, 29).

COMPLETELY REPLACES cocaine in surface anæsthesia and is free from the major disadvantages of cocaine (7, 21, 28).

THE PERCAINE HANDBOOK

A comprehensive and fully documented 52-page survey of the Pharmacology, Toxicology and Clinical Applications of Percaine will be sent on request.

The whole of a great medical
story told for the first time

SIR BUCKSTON BROWNE

LL.D., F.R.C.S.

pays a striking tribute to

Dr. Bradley Remembers

by **FRANCIS BRETT YOUNG**

*A book which "should be read by every student of
medicine, every practitioner, every surgeon" . . . and
which is moreover the best selling novel in England.*

IN A LETTER to the publishers, here quoted by kind permission, Sir Buckston Browne writes: "In *Dr. Bradley Remembers*, Dr. Francis Brett Young has surpassed himself. It is charmingly written and full of human interest, and in every way must appeal to the general public. Moreover it should be read by every student and every young practitioner of medicine . . . Full of wisdom which every young doctor will read with profit . . .

The book is also an important historical document. The great surgical event of the nineteenth century was the establishment, all over the world of 'Listerism', founded upon Pasteur's immortal bacteriological investigations. It had been considered a law of Nature, that open wounds must, almost invariably become, sooner or later, septic, and a large percentage of victims die in torture and anguish. All this has been swept away by 'Listerism'. At first Mr. Joseph Lister, afterwards Lord Lister, met with bitter opposition from his brother surgeons. The whole of this great story is told, almost for the first time, by Dr. Brett Young. The conditions of surgical wards before and after the victory of 'Listerism' is graphically described. The book should be read and preserved by all young surgeons.

Finally, the book is valuable as showing the hard, ill-paid, daily and nightly toil of the General Practitioner or family doctor to whom all sooner or later have to be grateful—men, and now women, who are the very backbone of a beneficent profession."

COLD WEATHER AILMENTS

DECEMBER, 1938

The December number of *The Practitioner* contains a symposium on winter ailments. The modern treatment of pneumonia, bronchitis, influenza, and the common cold is described by experts

PRINCIPAL CONTENTS

THE MODERN TREATMENT OF PNEUMONIA IN GENERAL PRACTICE

By G. E. Beaumont, D.M., F.R.C.P., *Physician, the Middlesex Hospital, the Brompton Hospital for Diseases of the Chest, and the Royal Masonic Hospital.*

THE MANAGEMENT OF CHRONIC BRONCHITIS IN THE WINTER

By F. H. Young, O.B.E., M.D., F.R.C.P., *Consulting Physician, Charing Cross Hospital, Physician, the Brompton Hospital for Diseases of the Chest; Medical Officer in Charge of the Tuberculosis Dispensary, St. Bartholomew's Hospital.*

CLINICAL ASPECTS OF INFLUENZA

By J. G. Scadding, M.D., M.R.C.P., *First Assistant, Department of Medicine, British Postgraduate Medical School.*

VACCINES AND THE COMMON COLD

By Dennis Embleton, M.A., M.B., *Assistant Lecturer in Bacteriology, University College Hospital Medical School, London.*

WINTER DIARRHOEA IN INFANTS

By Stanley Graham, M.D., F.R.F.P.S., *Visiting Physician, the Royal Hospital for Sick Children, Glasgow; Lecturer on Medical Diseases of Infancy and Childhood, University of Glasgow.*

SKIN DISEASES IN THE WINTER

By H. D. Haldin-Davis, M.A., M.D., F.R.C.P., F.R.C.S., *Physician, the Hospital for Diseases of the Skin, Blackfriars; Consulting Dermatologist, Royal Free Hospital.*

DIET IN WINTER AND SUMMER

By V. H. Mottram, M.A., *Professor of Physiology in the University of London; Head of the Departments of Dietetics and Physiology, King's College of Household and Social Science, London.*

This number also contains practical articles on the following subjects:

THE TREATMENT OF PAIN IN SEVERE INJURIES.
PAINS OF SIGNIFICANCE TO THE SURGEON.

DISEASES OF THE EYE.
THE PREVENTION AND CONTROL OF PUERPERAL SEPSIS.
GASTRO-ENTERITIS.

120 pages of text. Price 4s. post free.

The January 1939 issue will contain a symposium on
DISEASES OF THE SKIN.

ORDER FORM

To the Publishing Department,
The Practitioner,
5, Bentinck Street, London, W.1.

I enclose £2 2s. Please send to me *The Practitioner* post free for one year, beginning with the number; subscription to include two Special Numbers without extra cost.

'I'm no doctor,'

says Mr. Therm

'But I can help the doctors!'

Mr. Therm, the well-known representative of the Gas Industry, has noticed what formidable obstacles the Medical Profession has to overcome in its work of making England healthier. He has observed that long established human habits—even when they are a hindrance to health—are very hard to eradicate. For example, much illness is due to the fog and grime that foul the air of English cities. 70% of this 'aerial sewage' comes from home fires. Yet it is not easy to persuade people that they should give up their smoky, old-fashioned fires and help to clean the atmosphere and improve their own and other people's health by using gas and coke—the fires without smoke. Of course, Mr. Therm is commercially interested in promoting the use of gas and coke fires, but he is spurred to greater efforts by the knowledge that smoke abatement is of national importance. And he is at present conducting a new and vigorous campaign—one of the advertisements is reproduced above—which he hopes will have the encouraging approval of the Medical Profession.

INSTANT
and nearly
BOILING
WATER

*Clean
because its
electric*

Electricity brings to the surgery of every doctor and dentist instant, clean and nearly boiling water—an essential.

A 11-gallon "Charlton" Electric Water Heater, with its gleaming white finish, consumes only three to four units per day. The water can be used for drinking or mouth-wash, for the inner container of the heater is immersed in a bath of the purest tin during manufacture.

Once the heater is installed over a sink or wash-basin, it will go on working entirely automatically and using electricity only when the water falls in temperature.

No flue is required for there are no fumes, no radiated heat; four bolts fix the heater.

To operate, just turn the tap—electricity has done the stoking!

FORGET ALL YOU'VE EVER HEARD
ABOUT ELECTRIC DRY SHAVERS

Because

THE MAKERS OF WORLD FAMOUS EVER-READY RAZORS AND BLADES OFFER YOU THIS PERFECTED EVER-READY ELECTRIC DRY SHAVER

HERE'S the first dry shaver by safety razor makers! The first dry shaver by people who've learnt about perfect shaving from thirty-six years of razor and blade making. Ever-Ready have taken up electric shaving, tackled it, perfected it—and here you have the splendid result!—and a coupon to help you find out more about it.

Why it is better: there are 70 'Magic Microtines' to guide each bristle into the right clipping position, yet guard your skin. So you can't help getting a close comfortable shave every time.

The Ever-Ready has a two-way shaving head, to make every motion an effective 'shaving sweep.' It has a non-skid grip, light weight, and it's suitable for A.C. or D.C. mains.

THE IDEAL CHRISTMAS GIFT

What better Christmas gift for any man of any age than easy shaving for life with an Ever-Ready Electric Dry Shaver?

Ever-Ready

electric dry shaver

The first electric dry shaver made by people
with 36 years of face shaving experience

On sale at all Stores, Chemists, Timothy Whites & Taylors and principal Boots branches.

Chapter 1 from BACK TO ACTIVITY★

1. Primary above-knee amputation showing typical flabby condition found in early stages. The stump is flexed and extension restricted. Note the terminal bulbous mass of loose flesh.

The preparation of the stump

2. The stump is bound so as to compress the flesh into the desired taper shape and exercised daily by means of the Desoutter Elastic Exerciser.

3. After 6 weeks' use of the exerciser. Note the extensive shrinking of the soft flesh and re-development of the muscles.

★ It is unfortunate that an amputation stump never takes its final shape and size until some six or eight months after first wearing the limb, and to that extent the first fit cannot be the final one. But much can be done to speed up the process of shrinkage. In Chapter 1 of "BACK TO ACTIVITY" Mr. Desoutter explains the methods of bandaging and exercising, and discusses how stump muscles can be developed, superfluous flesh reduced, and the tendencies to flexion and abduction counteracted. A copy of this book will gladly be sent on request.

Duo-Therapy sunshine for your patients

The illustration shows the combined actino-therapy technique used in treating lumbago, lumbar fibrositis, etc., applying (general) ultra violet irradiation with the Alpine Sun Lamp and (local) infra-red irradiation with the Sollux Lamp. The Duo-Therapy Unit embodies both sources in one assembly.

There is no reason why you should go without the benefits which actino-therapy brings to both practitioner and patient. But your results depend largely on effective apparatus. No skill or study will enable you to overcome self-imposed defects due to inadequate or outworn equipment.

Specify the Hanovia Duo-Therapy Unit and have a lamp which is

always dependable, always ready for use, always constant in its high intensity of ultra-violet radiation. Remember that this Unit combines the most modern ultra-violet ray lamp (the self-starting electronic Alpine Sun) with the standard therapeutic infra-red lamp (the new Sollux Lamp, Model V). So the Duo-Therapy Unit enables you to apply any group and combination of rays needed for modern actino-therapy, in full therapeutic intensity, following the best technique, and using a dependable, responsive instrument.

This is why most practitioners now specify the Duo-Therapy Unit for their consulting rooms, and why so many users of older ultra-violet lamps avail themselves of our part-exchange terms for replacement with this up-to-date unit.

The Coupon is for your convenience.

A HANOVIA PRODUCT

A comprehensive Guaranty, full operating instructions, technical aid when needed, a complete 185-page Handbook of Technique, and enrolment for special actino-therapy magazine, are furnished free to every professional user of Hanovia equipment, anywhere in the British Empire.

The Hearing Aid Par Excellence

BONOCHORD

P. 3

Vest Pocket Valve Amplifier

SMALL AS A MICROTELEPHONE, YET WITH THE
HIGHEST OUTPUT EVER OBTAINED FROM
A POCKET VALVE DEAF AID.

Since their introduction the main obstacle to the general use of valve amplified deaf aids has been their bulk and weight. Attempts have been made to produce them in a form suitable for wear on the person without inconvenience, but in every case performance has been sacrificed to size, or the instrument has been ungainly for pocket use.

The BONOCHORD P3 is a 3 valve amplifier with piezo-electric microphone, which will fit *easily* into a waistcoat pocket, with separate batteries. Special valves designed for us have made this possible, together with the use of small components developed by our Research Department. In spite of its small size the aid has the amazingly high maximum output of 60 decibels. Let us send you full details of this new instrument, which we believe will do much to establish the general use of valve aids.

KOROMEX METHOD

The Koromex Occlusive Diaphragm is made in a range of sizes to fit each individual patient; pure latex rubber pessaries. Light and comfortable; practically unfelt. Two-year durability guaranteed. Practitioners and birth control clinics, for more certain protection, prefer to use the perfect fitting Koromex Diaphragm with

KOROMEX VAGINAL JELLY

Stainless and prolonged effective spermicide. The carefully gauged viscosity of Koromex Jelly affords the all-important mechanical block. No toxicity or irritation . . . makes the diaphragms easier to insert.

Advise the Koromex Method. Your patient will be grateful.

A sample of Koromex Jelly will be sent on application to medical practitioners; also a booklet, the Physician's Guide, on the technique of fitting the Occlusive Koromex Diaphragm. No charge. Write to

The Highest Record of PROVEN SUCCESS in Contraceptives

- Evidence of the high degree of efficacy of the Koromex Method is based upon the experience of 234 clinics—140 hospitals—over 50,000 physicians.

THE KOROMEX METHOD

KOROMEX DIAPHRAGM + KOROMEX JELLY

- The Koromex Diaphragm appears on the National Birth Control Association's approved list with seven Prentif products, including Condoms, Sheaths, Jellies and Suppositories. Illustrated descriptive Price List on request.

Relief from Physical and Mental Discomfort during the Menstrual Period

TAMPAX ★ SANITARY PROTECTION WORN INTERNALLY

The efficacy and safety of the vaginal tampon for the purpose of absorbing cervical discharges at the site are recognised by every doctor. Realising that the application of the same principle to menstrual hygiene would spare the patient much local discomfort and minimise risk of infection, a physician designed an adaptation of the vaginal tampon for regular monthly use. Tampax is its perfected form.

Expanded Tampax in situ showing adaptation to the vaginal walls and distance from urethral orifice.

Tampax is made of long-fibred surgical cotton-wool, which has been sterilised and highly compressed. Each tampon is individually sealed within its own patented applicator which enables every user to insert it in the proper position without contact with the hands. It is removed simply by means of a cord sewn through the cotton-wool by an exclusive stitching process which makes disintegration impossible.

Each tampon has an absorption capacity of 1-1½ ounces. As it absorbs the fluids, the tampon opens gently to a soft mass, comfortably adapting itself to the size and form of the vaginal walls. Irritation and chafing are thus eliminated. As the tampon is contained in

the vagina away from contact with the urethra, contamination from this source is minimised. Infections of rectal origin are likewise avoided.

Tampax ensures the maximum cleanliness and comfort, and affords complete protection. Tampax may confidently be recommended for use by married women during normal menstruation. Its use by unmarried girls should not be advocated when the size of the hymenical aperture would cause difficulty in insertion and withdrawal.

We will be glad to send doctors a full-size package of Tampax, together with a folder giving more details, on request to Tampax Ltd., 10, Bolton Street, London, W.1.

SORE THROAT

THE 'PLUS' PROPERTIES OF T.C.P.

destroy bacteria

T.C.P. has an R.W. coefficient of 10 (dry salt). Its efficient bactericidal properties are due to its unique organic combination of chlorine and iodine. Its antiseptic action is not impaired by contact with body fluids.

relieve dysphagia

The salicyl radicle in the T.C.P. molecule exerts a marked analgesic effect and this, coupled with its excellent penetrative power, ensures quick relief of inflammatory oedema and the resulting dysphagia.

T.C.P. is a safe antiseptic for use as a routine gargle or spray, in inflammatory and infective throat conditions. It does not irritate or injure the most sensitive tissues.

A clinical sample of T.C.P. may be obtained by any physician from:— British Alkaloids Ltd., Datchet House, London, E.C.2

T.C.P. THE *plus* ANTISEPTIC

RADIOSTOLEUM

(Standardised Vitamins A and D)

*The guardian of

CONVALESCENCE

To be able to recommend, in cases of convalescence, a tea which is readily assimilated by the weakest stomach is undoubtedly an advantage.

There is such a tea with juices milder — much milder — than those which the astringent varieties contain.

This pure tea, "TY-PHOO" TEA, is grown upon the mountains of Ceylon and mainly consists of the delicate edges of the tea leaf; hence its difference.

Write to:

Sumner's

"Ty-phoo" TEA

OVALTINE

BEFORE AND AFTER OPERATIONS

THE use of 'Ovaltine' before a major operation is of great service in helping to build up the system against the strain involved by operative interference. In abdominal cases especially, where a light and unirritating diet is necessary, the use of 'Ovaltine' alone for a few days before the operation will be found sufficient to maintain the patient's nutrition at a sufficiently high level.

After severe operations, the regular use of 'Ovaltine' is of the greatest service on account of its bland nature, its ready digestibility and its highly nourishing and sustaining properties.

'Ovaltine' is a complete food, composed of fresh, full-cream milk, eggs and malt extract, in the form of crisp granules which dissolve readily in milk to form a delicious beverage acceptable to the convalescent patient.

A liberal supply for clinical trial sent free on request.

GERMICIDAL EFFICIENCY maintained in the presence of organic matter.

In the conduct of labour 'Dettol' possesses marked superiority over carbolic and cresylic antiseptics. 'Dettol' has a Rideal Walker co-efficient of 3.0, yet 'Dettol' can be used at really effective strengths — without discomfort, danger or staining. 'Dettol' maintains high bactericidal efficiency in the presence of blood and other organic matter. 'Dettol' is a clean, clear, non-poisonous fluid — with a distinctly pleasant smell.

Sold by Chemists and Medical Suppliers in bottles, 1/-, 1/9, 3/-, 5/- and 7/6, and in larger sizes for Medical and Hospital use. These prices do not apply in Eire or Overseas. Sample, and full information on request.

Thorough
— but
pleasant!

In spite of very high germicidal efficiency, 'Dettolin' has a distinctly pleasant taste — an advantage which tends to ensure that the patient will gargle thoroughly and often. 'Dettolin' is specially made to deal with the micro-organisms concerned in affections of the mouth and throat — made so that it is soothing and gentle on delicate mucous membrane. 'Dettolin' contains among other ingredients the active germicidal principle of 'Dettol' — the modern antiseptic.

*'Dettolin' is obtainable from Chemists and Medical Suppliers.
Price 9d. and 1/3. Sample, and full information on request.*

Works: King's Langley, Hertfordshire.

A major operation in progress in the operating theatre of a London Hospital.

ANTISEPTIC PROTECTION IN THE THEATRE

THE greatest danger in any operation is the risk of introducing bacterial micro-organisms into the system. Because of this, elaborate precautions are taken in the operating theatre to prevent infection. Modern antiseptic methods have succeeded in eliminating sepsis—once the surgeon's greatest fear and problem.

Risks of infection in everyday life, though less serious, are more numerous. In ordinary hygiene prophylactic measures cannot, of course, take the elaborate lines of the operating theatre, but fortunately the simple use of soap and water usually affords adequate protection against most forms of infection. But the degree of protection naturally depends on the antiseptic, antipruritic and germicidal qualities of the saponifying agent.

Wright's Coal Tar Soap has enjoyed the confidence of the medical profession for purposes of general protection for over 70 years. It has substantial

antiseptic and antipruritic qualities, and to-day, besides being specified by leading bacteriologists as the ideal everyday safeguard against infection, is used (according to the 1932 investigation of the Institute of Industrial Psychology) by doctors themselves more than any other brand of toilet soap. Wright's is the *only* soap to contain 'Liquor Carbonis Detergens' (Wright's), the valuable therapeutic used and recommended by eminent dermatologists. You can have every confidence in using Wright's in *your* practice and recommending it to *your* patients.

PROGRESS IN Biological Therapy

BIOLICAL investigation was commenced by Parke, Davis & Company forty years ago. In 1898 the firm produced the first 2000-unit per c.c. diphtheria antitoxin ever obtained. Biological work developed so extensively that soon after a biological farm was established for the production of serums, antitoxins, etc., and from that time Parke, Davis & Company have built up a reputation for biological products that is without equal. Progress in this department of medicine is active, and constant study is directed towards the elucidation of the many problems relating to serum production; *e.g.*, improvements in culture media, reduction of protein content and volume of dose of antitoxins. The introduction of an active meningococcus antitoxin is one of the firm's recent achievements.

Making Milton, the non-caustic hypochlorite . . . in stable form and at standard strength . . .

You know Eusol. But do you know Milton? Milton is a hypochlorite antiseptic of a far more satisfactory nature than Eusol, which is in general hospital use. Whereas Eusol must be freshly made each day, Milton (prepared by electrolysis, which gives it increased chemical activity) is subjected to a process which, for all practical purposes,

ensures its complete stabilisation for at least two years, if kept in non-actinic containers. Milton possesses all the remarkable germicidal and cleansing properties of the hypochlorite class of antiseptic, yet contains no caustic elements in its composition. In London alone, 47 hospitals now employ Milton in general use.

Battery of motor generators used for the manufacture of Milton by a special electrolytic process.

The electrolyzing tanks.

INDICATIONS

GARGLING.—As a prophylactic measure or as routine treatment of infection.

CATARRH.—A solution not exceeding 5% is most efficacious when applied by spraying. The special Milton Nasal Spray (3/- from all chemists) may be prescribed.

DOUCHING.—Milton is alkaline, deodorant, germicidal, miscible with mucus and pus; harmless to delicate internal membranes.

WOUNDS, CUTS, SCALDS.—The hypochlorite characteristics of Milton are invaluable for cleansing and sterilizing.

Members of the Medical Profession are invited to write to Medical Dept., Milton Proprietary Ltd., John Milton House, London, N.7, for free professional sample bottle of Milton and informative literature and copies of independent laboratory reports . . . or to arrange a visit to John Milton House.

The Appetising Four-Vitamin Malt Food

NUTRIENT PROTECTION

In a basis of good malt extract, appetisingly flavoured, Ostomalt provides four vitamins that a child needs — vitamins that are so often deficient in winter diets. Ostomalt provides vitamins A, B, D and also C — in balanced *standardised* form, together with a useful supplement of calcium glycerophosphate. Moreover, the easily digested malt extract of Ostomalt gives the 'body' to this

preparation to make it substantial fuel for growing needs. Ostomalt is most economical in use, being three times as potent in vitamins A and D as the best malt-and-cod-liver-oil product. One *teaspoonful* takes the place of three *tablespoonfuls*.

PRODUCT OF THE
GLAXO LABORATORIES

OSTOMALT

In 4-lb. jars, 1/9; in 1-lb. jars, 3/-; in 7-lb. jars, 17/-.

THE SEPTIC HAND*

BY THE LATE

SIR DAVID WILKIE, M.D., Ch.M., F.R.C.S.

Professor of Surgery, University of Edinburgh

A discussion on the septic hand cannot fail to be instructive, because, in the first place, it makes us clarify and bring into focus our views on acute infections and the principles on which they should be treated, and, in the second, it brings into prominence an oft-neglected but all too common problem of everyday practice.

There has been an unfortunate tendency to regard infections of the hand as among the minor surgical maladies. In point of fact such infections are of primary importance, for not only do they not infrequently endanger life but quite commonly they lead to lasting disability in men who have to earn their livelihood by manual work. Rational treatment of such infections will depend (a) on a sound knowledge of the infective process, and (b) on a familiarity with the anatomical structure of the hand and the relation of this to varied types of infection. We owe a great deal to two men for our modern treatment of hand infections—to Bier for his illuminating studies of the infective process, and to Kanavel for his contribution to the pathological anatomy of the infected hand.

The Infective Process

Mild infections of the hand are of hourly occurrence, although but a very small proportion of them ever reach the doctor. There is obviously a considerable local and general immunity against the stray bacteria found on our hands and on the varied objects which may inflict an accidental wound. Every now and then, however, a germ of some virulence gains access, or a wound with devitalized edges presents a soil in which otherwise harmless germs may flourish and we recognize that infection has gained a hold. The signs of such a foothold are local pain and swelling, and the general evidence of poisonous absorption, such as rigor, rise of temperature and pulse, and dryness of the tongue and mouth.

In the mildest degree of infection the local defence mechanism appears to be easily capable of dealing with the invading germs. The transient blush, which means that the local vascular and cellular reactions have quickly overcome the invaders and restored the part to normal, has a lesson for us in the treatment of infections. Local hyperaemia permits a rapid concentration of defences and

confines the fight to a little zone around the point of entrance of the germ. If we could restrict the area of infection to the tissues round about the point of entry, if we could have the fight fought to a finish in the outskirts and preserve intact the inner defences and the citadel, we should have an almost painless victory with the minimum of loss.

Bier's great contribution to the study of infection was his demonstration that, by controlling the return circulation of blood and lymph from an infected part and producing a slight lymph stasis in the area, we may not only limit the central spread of infection until such time as the process of immunity is fully under way, but we may by bathing the infected area in lymph dilute the poisons, reducing pain and favouring recovery with a minimum of tissue damage by suppuration or necrosis. In this country his message was understood imperfectly, and "Bier's congestion" was taken to imply a venous stasis induced by elastic constriction verging on the degree

Fig. 1.—Bier's bandage applied to the upper arm. (The bandage is applied direct to the skin and secured by a small bit of adhesive strapping. There is no blueness or swelling of the forearm.)

at which capillary haemorrhage occurs. While Bier freely acknowledged that he got the idea from Thomas's method of treating delayed union of fractured bones and that he applied the short period of intense venous stasis in the treatment of tuberculous joints, he maintained that the method of using long-continued mild blood and lymph stasis in acute infections was a later evolution and a discovery of which he had reason to be proud.

If this discussion does nothing else than induce you to use mild passive hyperaemia in acute infections it will

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Plymouth, 1938.

not have been in vain. I consider that a Bier's elastic bandage is the most valuable piece of apparatus a practitioner can possess, with the obvious proviso that he knows how to use it.

Besides this principle of seeking to localize infection whilst immunity is rising, two others immediately suggest themselves. Can we do anything by way of the blood stream (a) to kill off the infecting bacteria; (b) to raise artificially the patient's immunity to their toxin? The era of effective chemotherapy would seem to have been inaugurated, and the discovery of the sulphonamide group of drugs has opened a new and hopeful chapter in the treatment of virulent infections. The use of antitoxic sera, although somewhat overshadowed during the past two years by chemotherapeutic measures, has now an imposing array of successes to its credit, and in severe infections of known character it should, if available, always be tried. Such measures as inducing free excretion by kidneys, skin, and bowels by copious libations of bland fluid, the replenishing of the liver by giving

pulp infection and the need for early opening when the infection gets a hold. We know the anatomy of the spread of pus in an acute paronychia, and the simple but important means of draining it effectively.

Acute Streptococcal Infection with Lymphangitis

When from a punctured wound or from a scratch virulent streptococci gain entrance to the tissues we may see within a few hours the evidence of their multiplication and their spread. The hot throbbing wound, the ache up the arm, the rigor followed by a sharp rise of temperature, indicate a severe infection. On examination there may be local redness and some oedema of a finger, some swelling of the dorsum of the hand, faint red lines up the forearm, and some tenderness in the axilla, all indicating a virulent and rapidly spreading infection. How is such infection best combated? The patient is put to bed and given copious diluent drinks. A warm moist dressing is applied to the hand and forearm and a few turns of a thin elastic bandage are wound *lightly*

FIG. 2.—Transverse section of upper arm. *a* = subcutaneous vein with accompanying lymphatics.

FIG. 3.—Section of arm with Bier's bandage applied. Note compression of superficial vein and lymphatics (*a*); the vessels beneath the deep fascia are compressed little if at all.

glucose in the drinks, favouring metabolism and sleep by sunlight and fresh air, all tend to aid the more specific forms of therapy.

The Pathological Anatomy

Kanavel, by his intensive study and analysis of hand infections and his differentiation of types and the anatomical approach in dealing with each, gave a new impetus and interest to the treatment. As in so many other regions of pathology, it is by the study of early stages that we observe the essential nature and the lines of spread of different infections. In the full-blown massive and oedematous infected hand it is oftentimes difficult to detect the true locus of the underlying infection. We have learned, however, to recognize the signs of tendon-sheath infection, of infections in the various palmar spaces, and of those in the deep forearm space. We now know the anatomical restrictions of the finger-

round the upper arm (Fig. 1). The bandage is applied direct to the skin in such a way that a gentle pressure obstructs the superficial veins and lymphatics and, without producing any blueness or duskiness, causes a mild lymph stasis in the limb (Figs. 2 and 3). The secret of successful application of the bandage is the abolition of pain. If pain is increased the bandage is too tight and must be reapplied. The elastic bandage may be left on continuously for forty-eight hours with advantage.

Recognizing from the physical signs the streptococcal nature of the infection, it is well to give without delay 30 c.c.m. of streptococcal antitoxic serum after desensitization. At the same time treatment with one of the sulphonamide preparations is instituted. A careful watch is kept for the development and localization of pus in the hand and forearm, but no great haste is made to interfere locally unless there be signs of a finger-pulp or tendon-sheath infection.

The effect of lymph stasis in localizing the infection is in my experience remarkable, and skill in the application of Bier's elastic bandage is a great asset to all who have to treat such cases. The decision as to when a studied conservatism should give place to active surgical intervention requires nicety of judgment, but as a general rule it may be said that delayed is wiser than premature incision.

Finger-pulp Infection

Owing to its peculiar anatomical structure the finger pulp demands special attention. The dense fatty layer which forms the pulp is broken up into compartments by fibrous septa, which further bind the skin down to the bone. Any infection, with oedema and effusion, produces great tension within the pulp. The terminations of the digital arteries, including the branch to the distal phalanx, traverse the pulp and are exposed to the tension within it. This may be so great as to compromise the blood supply to the phalanx, and necrosis results.

It is obvious, therefore, that special anatomical conditions here determine early intervention. If within thirty-six hours of the onset of pain there is no sign of amelioration an incision made on one side of the distal phalanx is carried well down into the pulp, opening up its spaces. A counter-opening on the other side of the phalanx is sometimes desirable. Even after opening the finger it is wise to continue with the fomentations and the passive hyperaemia.

Tendon-sheath Infections

Spread of infection to a tendon sheath is heralded by severe pain and interference with the function of the finger. This is held in a position of semiflexion. Any effort to straighten it causes acute pain. Definite localized tenderness is met with on pressing over the proximal end of the tendon sheath in the case of the index, middle, and ring fingers, and over the line of the sheath in the case of the thumb and little finger.

As soon as infection of a sheath is diagnosed a general anaesthetic should be given, a tourniquet applied to the arm, and an incision made along one side of the proximal phalanx of the affected finger. The bulging sheath is incised and, if purulent fluid escapes, further incisions may with advantage be made along the side of the second phalanx and in the palm. In the case of the thumb and little finger incisions must be made along the thenar and hypothenar eminences and at the wrist to drain the radial and ulnar bursae respectively. Hot saline baths and active movement of the fingers should be encouraged, as they favour drainage. Tubes and rubber drains are better avoided.

Palmar Space Infections

The infection of one or other of the palmar spaces, so clearly defined by Kanavel, may arise from an infected wound of the palm, by lymph spread from a finger, or by rupture of an infected tendon sheath. When due to the last-named the clinical features may be confusing, but the treatment is seldom in doubt. The spaces, being deeply situated, may contain pus under tension without obvious fluctuation being detectable. The dense palmar fascia offers an unyielding barrier to forward spread. The metacarpals and the interosseous muscles bar the way behind and pus is forced to travel along the lumbricals to the web between the fingers, where it bulges, points, and,

if not opened, bursts. The drainage of these spaces, either from the web back along the lumbricals or by incising the palm—preferably the former—will, as a rule, lead to rapid improvement if no tendon sheath has suffered.

Forearm Infection

In some cases, and particularly those of neglected tendon-sheath or palmar space infections, swelling and oedema of the lower part of the forearm may suggest a deep-seated cellulitis. Suppuration in Parona's space—that is, beneath the flexor muscles and tendons and in front of the pronator quadratus—is diagnosed. When oedema and redness involve the lower half of the forearm and considerable tenderness is elicited over the front of its lower third and above the carpal bursa, then one may rest assured that pus is collecting in the deep forearm space. Without delay this should be opened under a general anaesthetic with a free incision, laying open the abscess on one side and a counter-opening for a drain on the other.

Amputation of Fingers

With severe tendon-sheath infection, even after reasonably early opening, it is no uncommon thing to find one or both flexor tendons sloughed. Not infrequently along with this the first interphalangeal joint becomes involved, with softened ligaments, shedding of articular cartilage, grating, and lateral mobility. We should realize that a stiff or tender finger may be a crippling handicap to the labouring man. It is always a keen disappointment at the end of many weeks of painful dressings for him to find that his trouble and patience have been in vain and that amputation is necessary. Sloughing of tendons, if accompanied as it so often is by disorganization of a joint, should point to amputation without undue delay. Gangrene of the distal part of the finger, met with in severe infections, is another indication for amputation. Amputation should never be performed when the inflammation is at its height. A little delay is beneficial, and helps to avoid any flare-up or central spread of infection.

Indolent Infections

A not uncommon type of infection, especially among field workers, is one associated with brawny induration, little tendency to pus formation, and slight general reaction. The usual signs of tendon-sheath or palmar space infection are difficult to determine, and indeed may never develop. In such cases short-wave therapy has been found of material value, and, if available, should always be employed. In some cases the infection may slowly resolve without suppuration but with a considerable period of disability; in others pus may eventually form in the palm or in the forearm and require evacuation by incision. Complete recovery from such low-grade infections may take many months, but eventually may be complete.

Rehabilitation in Hand Infections

The acute phase of infection commands our interest and attention: all too often the slow, tedious phase of convalescence receives but scanty care. Almost without exception infections of the hand and forearm are followed by fibrosis with its attendant stiffness. The more protracted the suppuration the greater will be the resultant disability from cicatricial fibrous tissue. When pus has formed and has localized, generous incisions allowing of

the freest drainage will, by hastening resolution, diminish the subsequent fibrous contractures.

It is very desirable that those who are responsible for the treatment during the acute inflammatory phases should also supervise the subsequent treatment by physiotherapeutic means. While few would challenge the value of complete rest to the part during the early acute phase of inflammatory reaction, few would deny the benefits of active movement and of exercise once the florid spreading stage is over and the early dangers are past. Apart from the sloughing of tendons and the involvement of joints which give permanent stiffness, we have the adhesions in tendon sheaths, the fibrosis in the fascial planes between the muscles, the fibrous plaques which form where tissue was destroyed. If the thought of function be kept uppermost in our minds in conducting the treatment in the stages which follow that of the invasive process, we shall never permit the development of the unbreakable barriers to movement which determine crippledness in the neglected case.

The use of active and purposive exercise in restoring useful movement should govern the tedious period which follows that of nursing care. Massage and passive exercise have their place, but active movement, controlled and guided by the patient's will, is the effective element in treatment. If interest and achievement lend their spur to effort, the patient, progressing from one task to another designed to increase the range of certain movements, passes unconsciously from invalidism back to effective work. The workshop now forms an essential part of the equipment of the convalescent institution. Our responsibility for treatment does not end until the maximum of usefulness has been restored.

Summary

1. Acute infections of the hand should be treated in the first instance on conservative lines.
2. In very severe infections three measures may be employed: (a) lymph and venous stasis (Bier); (b) chemotherapy (sulphonamide); (c) passive immunity (antitoxic serum).
3. In certain areas—for example, finger pulp and tendon sheaths—anatomical considerations make early opening desirable.
4. As soon as the early dangers are past, efforts to restore function should begin, and they should end only when the maximum return of function that is possible has been attained.

At the eleventh British Congress of Obstetrics and Gynaecology, which, as already announced in these columns, is to be held at Edinburgh on April 4, 5, and 6, 1939, the chief subject for discussion will be pain in labour and methods of alleviation, to be introduced by Professor Chassar Moir of Oxford and Dr. John Sturrock of Edinburgh. The official guests of the Congress will be Professor Wagner (Berlin) and Dr. Samuel Meaker (Boston). Other communications will deal with genital hypoplasia, dysmenorrhoea, tubal infection, hyperemesis gravidarum, results of pregnancy toxæmia, trichomonas infection, male sterility, habitual abortion, and myometrial activity. A visit will be paid to the Department of Animal Genetics under the direction of Professor F. A. E. Crew. There will be a demonstration of pathological specimens, and those who desire to exhibit pathological material are asked to communicate with the local secretary of the Congress, Dr. Chalmers Fahmy, 7, Chester Street, F.R.C.S., to whom other information concerning the Congress may be obtained, and of those in the know the anatomical restrictions.

THE CORRECT NAME OF THE MALIGNANT TERTIAN MALARIA PARASITE

BY

SIR RICKARD CHRISTOPHERS, C.I.E., F.R.S.,
Colonel I.M.S. (ret.)

Leverhulme Fellow under the Medical Research Council,
London School of Hygiene and Tropical Medicine

AND

J. A. SINTON, M.D., D.Sc.,
Lieut.-Colonel I.M.S. (ret.)

Manson Fellow, London School of Hygiene and Tropical
Medicine

Not only is the malignant tertian malaria parasite referred to under a multiplicity of colloquial names, such as malignant tertian, subtertian, aestivo-autumnal, and "tropica," but even the zoological name of this species is a constant source of difficulty and doubt to those who have occasion to use it. Thus the name now in most general use is *Plasmodium falciparum*, but many authors employ the names *P. praecox* or *P. innocuum*, claiming that one or other of these is the correct specific designation. Uncertainty also exists as to whether this species should or should not be placed in the genus *Laverania*, and *L. malariae* and *L. falcipara* are names not uncommonly seen. Efforts to apply the rules of zoological nomenclature seem only to have added to the confusion.

The Present Position

Hitherto controversy has chiefly revolved around the question which of the specific names—*praecox*, *innocuum*, or *falciparum*—has the strongest claim to validity. Before any detailed discussion is entered into it is desirable first to review very briefly the present position in respect to these names. Grassi and Feletti (1890b) gave the name *Haemamoeba praecox* to a parasite found by them in the blood of birds from a certain malarious region in Italy, and also, later in the same paper, to the then newly discovered asexual stages of the parasite of aestivo-autumnal fever in man, believing the two parasites to be identical. Later Grassi and Feletti (1891, 1892) gave the name *relicta* to the same or a similar parasite in the blood of birds. Sergeant *et al.* (1929) consider that, although these authors gave the same name to the avian and the human parasite in the first place, they have by the subsequent naming of *relicta* automatically designated *praecox* as the human parasite, and that therefore the correct name for the latter species is *praecox*. This would be in accordance with a common procedure in zoological nomenclature—that is, where a name at first given has included two closely related species, one of which is subsequently designated by another name, the original name becomes applicable to the remaining species. Other authors (Schaudinn, 1903; Blanchard, 1905; Stiles, 1929) hold that the context in the original description shows that the name *praecox* was definitely given to the bird parasite, and that it must therefore be invalid for the human one, whatever subsequent procedure on the part of the authors may have been. In this case, if *praecox* be invalid for the human parasite, then some other name is required for it. Here again authors differ. Some hold with Schaudinn (1903) that the first valid name is *innocuum*, used by Grassi and Feletti (1892); others that this name is also invalid and that the proper one for the parasite is *falciparum*, given by Welch (1897). It is pointed out by Blanchard (1905)

* The junior author desires to thank the Royal Society of London and the London School of Hygiene and Tropical Medicine for the financial assistance which has enabled him to continue his work on malaria.

that the name *innoculatum* was used by Grassi (1891), previous to being given to the human parasite, to designate a blood parasite of a bird—the kestrel (*Cherchneis tinunculus*). In this paper Grassi goes on to say, just as was done with *præcox*, that he considers this avian parasite to be the same as the so-called “unpigmented parasite” reported in aestivo-autumnal fever in man, and on these grounds includes it in his list of human parasites. From such a point of view the name *innoculatum* must therefore be rejected for the human parasite for the same reasons as *præcox* was—namely, that the name was preoccupied by a bird parasite.*

The First Naming by Laveran

None of these arguments appears, however, to have sufficiently taken into account the circumstances relating to the first naming of the malaria parasite by Laveran, and the effect of such considerations upon the validity of the subsequent steps in nomenclature taken by Grassi and Feletti and others. In his book Laveran (1881a) gave the name *Oscillaria malariae* to the entirely new form of parasite discovered by him in the blood of malarial subjects. From the standpoint of zoological nomenclature everything depends on what description accompanied, or was referred to at, this first naming. It is immaterial what subsequent procedure in this respect was adopted by Laveran or any other author. Thus that Laveran later discarded the name *Oscillaria* as unsuitable has no relevance in deciding upon the correct nomenclature of this parasite. Also if the description clearly indicates the malignant tertian parasite and no other, then *malariae* is by right of priority the specific name of the malignant tertian parasite, independently of whether Laveran thought of the malaria parasite at the time as one or more species. Also if this description does so apply, then not only could there in this case be no other name having priority, but in no circumstances whatever should any other specific name (for example, *falciparum*) rightly replace it.†

After a careful examination of the original publications we have convinced ourselves that Laveran's description, given at the time of naming, relates with absolute certainty to the sexual forms of the malignant tertian parasites and to these only, whilst even in somewhat later descriptions (1882-4) no forms which can with certainty be assigned to any other species are included. The various descriptions given by Laveran at this period relate to four types of bodies, regarding which it is possible to say that bodies No. 1 were typical crescents, bodies No. 2 were exflagellating spheroid bodies, and bodies No. 3 “cadaveric forms” of Nos. 1 and 2. It is clear that all these forms were malignant tertian sexual forms. Laveran (1887) says: “A côté des éléments cylindriques en croissant on trouve presque toujours des corps ovalaires (E, fig. 4) qui paraissent être des formes intermédiaires aux corps sphériques et aux corps en croissant” (loc. cit., p. 270), and, in his book (Laveran, 1881a, p. 97), that “les éléments parasitaires du sang qui sont décrits dans ce travail sous les noms de corps No 1, No 2, et No 3 ne représentent probablement que trois phases du développement d'un seul et même parasite comparable aux oscillariées, vivant à l'état d'agglomération ou d'enkystement pendant une partie de son existence.” Only in regard to bodies No. 4 can there be any doubt as to these not being forms of malignant tertian. These forms

(No. 4) are, however, not mentioned in the description which accompanied the first giving of the name *Oscillaria malariae*. The reference commonly given in literature to such naming is “Laveran, 1881.”

Two papers published in that year in scientific journals (vide Laveran, 1881c, 1881d) do not include any scientific naming of the parasite. Only in Laveran's book (Laveran, 1881a), which we had some trouble to obtain, is the name *Oscillaria malariae* given, as later referred to by Laveran himself and others (Richard, 1882, 1883). The words used are: “S'il était démontré que les filaments mobiles des corps No 2 sont bien réellement de l'espèce oscillariées, le nom d'*Oscillaria malariae* conviendrait bien au nouvel hématozoaire” (loc. cit., p. 87). From this it is evident that the name *Oscillaria malariae* was applied to the microgamete which Laveran believed to be the mature form of the parasite. All the forms described by him in this connexion—namely, bodies Nos. 1, 2, and 3—have been universally accepted by subsequent workers as sexual forms of the malignant tertian parasite. As regards bodies No. 4 (intracorpuseular forms) it is perhaps now impossible to say what species they represent, but it is by no means impossible that these also are forms of the malignant tertian parasite, for Laveran notes that he originally worked especially with material obtained from the organs of patients dead from pernicious fever (Laveran, 1882), and the larger intracellular forms figured by him are compatible with developing crescents or even older schizogonous stages of malignant tertian. No one can say that they are with certainty any other particular species (vide later remarks in this paper *re* the quartan parasite). Laveran then, when naming the parasite, was certainly mainly concerned with, if his descriptions did not entirely relate to, the malignant tertian parasite. He himself, when referring to some doubts as to the subsequent nomenclature, says: “J'ai décrit le premier les hémamibes comme les corps en croissant” (Laveran, 1891; footnote to p. 93).

Grassi and Feletti's Classification

Even, however, if it be not granted that Laveran's description of *malariae* referred to the malignant tertian parasite, this specific name would still hold good, since, as we shall see, at a later date it was clearly designated as this parasite by Grassi and Feletti; for it is laid down that if two or more species have been included in an author's description under a given name (as has been maintained by some workers in regard to Laveran's name, but we believe without justification), and the same or another author later designates (as we shall show was done by Grassi and Feletti when they recognized the name *Laverania malariae* as pertaining to the forms seen by Laveran) one of these species as that to which such name applies, then this name for the designated species is valid, unless invalid on other grounds.

With such evidence as we have indicated above, we think that in ordinary zoological procedure Laveran's designation of the malignant tertian parasite as *malariae* would have been accepted unreservedly. Why, then, should subsequent authors maintain that Laveran described only the malaria parasite “in general” or the quartan in particular (vide the usual textbook statements)? It seems clear that this was done *not* on the merits of Laveran's description but in order to clear up difficulties in nomenclature subsequently created.

The clue to the confusion is to be sought in the names given to the parasites in the years 1890-2, when Marchiafava, Celli, Bignami, Grassi, Feletti, and other famous workers in the field of early malaria research made their pioneer observations. It is because it is difficult, looking back, to realize what the facts appeared like to these observers that we must be careful not to make unwarranted deductions based upon our present knowledge of these parasites.

* Workers using the name *innoculatum* for the human parasite usually refer to it as *Plasmodium innoculatum* (Gr. & Fel., 1892), whereas it should be *P. innoculatum* (Grassi, 1891), if this name is to be used at all.

† Vide Article No. 25 of the Rules of Zoological Nomenclature, which reads as follows: “The valid name of a genus or species can only be that name under which it was first designated, on the condition: (a) that this name was published and accompanied by an indication, or a definition, or a description; and (b) that the author has applied the principles of binary nomenclature.” For case of reference to these rules the reader should consult Wenyon (1926) (p. 1336).

In 1890 Feletti and Grassi, from observations on the parasites of birds from healthy and malarious localities, and as a result of what was then known about the human malaria parasites, came to the conclusion that there were two kinds of these parasites—namely: (1) those resembling amoebae, which they called *Haemamoeba malariae* and which in man gave rise to the regular fevers (quartan and tertian); and (2) others of a peculiar morphology and character, as described by Laveran, which they called *Laverania malariae* and which they considered to be the cause of the irregular fevers. In the same year Grassi and Feletti (1890b), in a remarkable appendix added to the French transcript of an original paper in Italian (Grassi and Feletti, 1890a), (i) gave names to the two species of parasite (included in *Haemamoeba malariae* Feletti and Grassi, 1890) as shortly before differentiated but not named specifically by Golgi (1889)—that is, *H. malariae* (of quartan fever) and *H. vivax* (of tertian fever)—and (ii) added a third species, *H. praecox* (of quotidian fevers).^{*} In the following year Grassi (1891) named yet another species, *H. immaculata*, also a parasite of the quotidian fevers. These last two species (*praecox* and *immaculata*), in so far as they can be held to apply to the human parasites, related to the asexual forms of the malignant tertian parasite of which Laveran had already described and named the sexual stages, though at that time this relationship was unknown to Grassi and Feletti. We have, then, in 1892 five names assigned to the malaria parasites of man, as set out by Grassi and Feletti (1892):

Laverania malariae. (The sexual forms of the parasite of malignant tertian malaria.)†

Haemamoeba malariae Grassi & Feletti. (The parasite of quartan malaria.)†

Haemamoeba vivax Grassi & Feletti. (The parasite of benign tertian malaria.)†

Haemamoeba praecox Grassi & Feletti. (Name applied to a parasite of birds and also to the asexual forms of the malignant tertian parasite.)†

Haemamoeba immaculata Grassi & Feletti. (Name applied to a parasite of birds and also to the asexual forms of a supposedly special type of the malignant tertian parasite.)†

Of these specific names the first stands, for we have shown that it was clearly given by Laveran to the sexual forms of the malignant tertian parasite and that there could be no question of any previous name. *H. vivax* remains valid for the so-called benign tertian parasite. *H. malariae* Gr. & Fel. (nec *H. malariae* Laveran) would also be valid to this day as applied to the quartan parasite, provided *Laverania* and *Haemamoeba* (= *Plasmodium*) are retained as two separate genera.

Classification in One Genus

At the present time probably very few authorities would support *Laverania* as a genus desirable on morphological grounds. Both Schaudinn (1903) and Blanchard (1905) thought that Grassi and Feletti were not justified in separating the genus *Laverania* from the genus *Haemamoeba* (= *Plasmodium*), and considered that all the human malaria parasites should be included in one genus—*Plasmodium*. This is the common usage at present. Schaudinn (1903) and Blanchard (1905) state that when *L. malariae* is absorbed in the genus *Plasmodium* the specific name *malariae* lapses for the malignant tertian parasite, because there is already a *malariae* (the quartan parasite) in the latter genus. This is an incorrect procedure, for it is the more recent specific name (that is, *malariae* for the quartan parasite) which should lapse in conformity with Article No. 35 of the Rules of Zoological Nomenclature, which reads as follows:

^{*} Later in the same year a similar classification was republished by these authors (Grassi and Feletti, 1890c).

† The remarks in parentheses are ours.

"When, in consequence of the union of two genera, two different animals having the same specific or subspecific name are brought into one genus, the more recent specific or subspecific name is rejected as a homonym."

It is clear, therefore, that when one genus only is recognized for the human malaria parasites, the two names—*P. malariae* (Laveran) for the malignant tertian parasite and *P. malariae* (Gr. & Fel.) for the quartan one—cannot both be retained. In such a case, then, *P. malariae* (Gr. & Fel.), as applied to the quartan parasite, must sink as a synonym.

It is very interesting to note that Grassi and Feletti (1890b, 1890c, 1892) were perfectly correct in their procedure in giving their own name, *malariae*, to a parasite in what they considered to be another genus than that which contained Laveran's *malariae*, and that any error in this matter was one on the part of subsequent authors, who thought the name *malariae* Gr. & Fel. should obviously be *malariae* Laveran. It is a curious error, and one which has given rise to the erroneous solution of the puzzle in nomenclature by which the facts are squared only through maintaining that Laveran gave the name *malariae* to the malaria parasite "in general." Such a solution ignores the fact that *Haemamoeba malariae* Gr. & Fel. is a perfectly correct name so long as *Laverania* is maintained as a genus distinct from *Haemamoeba* (= *Plasmodium*). This error also logically demands the assigning to Laveran of the name of a species (the quartan parasite) which it is problematical to have seen at the time he gave the name *Oscillaria malariae*, and which he certainly did not then describe in such a way that it can be asserted that it was included in his original description of the malaria parasite.*

When, therefore, Grassi and Feletti recognized *Laverania malariae* as Laveran's species and erected two other species—*Haemamoeba malariae* Gr. & Fel. and *Haemamoeba vivax* Gr. & Fel.—they clearly designated (even if it be considered that Laveran had not already done so) the malignant tertian parasite as Laveran's species—that is, as the *malariae* which carries priority in any genus in which it may be placed.

We have endeavoured to ascertain at what period the specific name of the quartan parasite was changed from *malariae* (Gr. & Fel.) to *malariae* (Laveran), the former being perfectly correct so long as two genera are recognized, the latter totally erroneous whatever generic divisions be adopted. This error appears to have arisen about 1900, when Lühe (1900) speaks of the quartan parasite as "*Plasmodium malariae* (Laveran) s.str." In his classification of the malaria parasites a similar nomenclature is used by Schaudinn (1902), who designated under the name *Plasmodium malariae* (Laveran) the quartan parasite as the type species of the genus *Plasmodium*. Before this date we have been unable to find the name

* Some workers appear to believe that the parasite first observed and named by Laveran was the quartan one. There is no doubt that this author (Laveran, 1891) figured and referred to certain parasitic forms ("bodies No. 4") from a case of quartan fever, which strongly suggest segmenting forms of this plasmodium. He goes on to say, however, that such bodies were seldom seen by him, and assigns to them a very secondary place. He also states that these forms were seen in the blood of a case studied by him in September, 1881, and the protocols of his cases suggest that the exact date was September 17 (vide Case No. XXXIV, loc. cit.). We can find no mention of such forms in the book that contains his original definition of *Oscillaria malariae* (Laveran, 1881a), which book he presented to the Académie de Médecine on May 3, 1881, apparently before he encountered the quartan-like forms depicted by him. It seems very improbable, therefore, that this author had noted such forms when he gave the name *O. malariae* to the parasites discovered by him. Such a conclusion is strengthened by the fact that in his paper of October 24, 1881 (Laveran, 1881b), he speaks of bodies No. 4 for the first time. From a very careful study of his early works we have been unable to find any description of parasites which are clearly recognizable as quartan, either before or at the time when he first used the name *O. malariae*. We can therefore discover no foundation for the belief that the parasite first observed and described by Laveran was the quartan one.

malariae, as used for the quartan parasite, attributed to any other authors than Grassi and Feletti, whilst after this date the name *malariae* (Laveran) appears to have been generally adopted by workers in most countries (vide Stiles and Hassall, 1925; Wenyon, 1926; Doflein, 1929; Muhlen, 1931; Brumpt, 1936). Although Opinion No. 104 of the International Commission on Zoological Nomenclature (1928) gives *malariae* (the quartan parasite) as the type species of the genus *Plasmodium*, no author is quoted.

It follows, if *P. malariae* (Gr. & Fel.) cannot be used correctly for the quartan parasite, when only one genus is recognized, that the correct name of this parasite must be the next valid name given to it. Unfortunately Golgi (1889), who actually differentiated the quartan and the benign tertian parasites on their morphological characters, did not give these any other names than "parassiti malarici nella febbre quartana" and "parassiti malarici nella febbre terzana," which designations are not in Linnaean form and therefore are not valid in scientific nomenclature. The first authors to employ a correct Linnaean nomenclature for the quartan parasite seem to have been Celli and Sanfelice (1891), who used the name *Plasmodium malariae* var. *quartanae* for this species. We believe no objection can possibly be raised against the name *quartanae* as given in Linnaean form by these authors.* The correct specific name (*de jure*) for the quartan parasite appears, therefore, to be *quartanae* Celli and Sanfelice, 1891.

-The Genus *Oscillaria*

It is still necessary to consider the validity of Laveran's genus *Oscillaria*. It is generally accepted that this name is invalid because preoccupied by *Oscillaria* Schrank, 1823, given to a genus of algae. If this were the only ground of objection there could be no question that Laveran's name, being given to an animal, could not strictly be counted as preoccupied by a genus of the vegetable kingdom, though it is held undesirable to have the same name for two genera among the Protista. Actually it is certain from the context that Laveran in this case did not propose a new genus, but placed his parasite in that class of lowly organisms which at the time seemed to him most appropriate, this being Schrank's genus *Oscillaria*, which was erected for certain algae characterized by their peculiar animal-like movements. Even then, however, if one follows Article No. 1 of the Rules of Zoological Nomenclature, which reads thus:

"Zoological nomenclature is independent of botanical nomenclature in the sense that the name of an animal is not to be rejected simply because it is identical with the name of a plant. If, however, an organism is transferred from the vegetable to the animal kingdom its botanical names are to be accepted in zoological nomenclature with their original botanical status, and if an organism is transferred from the animal to the vegetable kingdom its names retain their zoological status."

It is difficult to see that Laveran's genus *Oscillaria* could rightly be considered invalid—in which case it would take precedence over *Plasmodium* Marchiafava and Celli, 1885. It is sometimes argued that the name *Oscillaria* is invalid because it was afterwards rejected by Laveran on account of inappropriateness; but, once given, even the author himself cannot reject a name for this reason (vide Article No. 32 of the Rules of Zoological Nomenclature).

It is not the intention of this paper to suggest that the names of the malaria parasites should be changed in accordance with the above findings. Such changes would now cause almost intolerable confusion. Fortunately they would not even be correct, for zoologists have agreed that

* Article No. 12 of the Rules of Zoological Nomenclature reads: "A specific name becomes a subspecific name when the species so named becomes a subspecies, and vice versa."

where a formal decision upon a name has been given by the International Commission on Zoological Nomenclature the name so fixed is the correct one for usage independent of all other considerations. Such a decision is given in Opinion No. 104 of this Commission (1928), which reads as follows:

"*Laverania* Grassi and Feletti, 1890a, 60, mt. *malariae* (homonym) so. *falcipara* Welch, 1897, 36, 47, type host *Homo*. (For authors who consider the parasite of aestivo-autumnal malaria generically distinct from that of quartan fever.)" Not *Laverania* Labbé, 1899a, 82, type *mnarum*, type host *Rana esculenta*."

"*Plasmodium* Marchiafava and Celli, 1885d, 791, mt., tsd. *malariae* (as restricted to quartan fever), type host *Homo*."

This decision does not prevent the sinking of *Laverania* Gr. & Fel., 1890* in *Plasmodium* March. & Celli, 1885, on zoological grounds unconnected with terminology. It does, however, clearly rule out *Oscillaria* Laveran, 1881, and also, arbitrarily and possibly wrongly but none the less authoritatively, all such questions of *de jure* nomenclature as have been discussed above. Nevertheless it ought to be pointed out that (1) apart from the malignant tertian parasite, there is in our opinion no description corresponding to *malariae* Laveran, 1881, and (2) the type species of the genus *Plasmodium* as recorded by Schaudinn (1903), by Blanchard (1905), by Stiles and Hassall (1925), and other authorities, is the quartan parasite, which has been given by them under the above *nomen nudum*.

Conclusion

Our object, then, in writing this note is to show how impossible at present would be the use of the correct names *de jure*, and the desirability of conforming to the agreed-upon convention of accepting names formally decided upon by the International Commission. The only loophole here would appear to be the possibility that, in the Opinion quoted, it is the generic names which are being fixed and that the validity of the decision does not extend to the specific designations given for the genotypes. This, however, would appear to be an objection overruled by the obvious need for uniformity and the opportunity of arriving at such uniformity on a reasonable basis given by the existing ruling. The only alternative would be a renewed application to the Commission (which perhaps is scarcely necessary, since usage in the main is now in accordance with what it would be desirable to recommend), that the names now most commonly used—that is, *P. falciparum* (Welch, 1897), *P. malariae* (Gr. & Fel., 1890), and *P. vivax* (Gr. & Fel., 1890)—be fixed by still more definite authority, the changes involved in a return to the strict *de jure* naming being too great a price to pay for theoretical correctness.

For the sake of clarity we append what we consider to be the nomenclature *de jure* and *de facto* of the three classical species, as this would be (a) if only one genus of malaria parasites be recognized, and (b) if a separate genus be used to include the malignant tertian parasite only.

* The usual authority given for the genus *Laverania* is Grassi and Feletti (1890). The first paper published by these workers in that year appears to be dated March 23 (Grassi and Feletti, 1890a), and in it they refer to the genus "*Laverania nobis*." The term *Laverania* is used, however, previously to this by Feletti and Grassi (1890), whose paper is reprinted from *La Riforma Medica* of January 15. The latter designation of the genus *Laverania* would therefore have precedence over that of Grassi and Feletti (1890a) so that according to this the genus should be *Laverania* Feletti and Grassi, 1890. On the other hand, Blanchard (1905) (p. 443 and footnote on p. 449) gives the first reference to the genus *Laverania* as follows: "R. Feletti et B. Grassi. *Sui parassiti della malaria*: 8° de 11 p., 22 déc. 1889.—La brochure est datée du 22 décembre, mais n'a été remise à la poste que le 30 décembre" ("distribuée le 30 décembre"). We have not been able to consult this pamphlet, but it would seem from this that the earliest authority for the genus *Laverania* is not Grassi and Feletti, 1890, but Feletti and Grassi, 1889.

the patient must be firmly discouraged, to diminish the risk of exhaustion, premature rupture of the membranes, cervical oedema, and consequent prolongation of labour. The temperature should be taken early in labour and hourly after rupture of the membranes. The maternal and foetal heart rates should be recorded hourly during early labour, half-hourly during the later first stage of labour, and quarter-hourly after the membranes have ruptured.

After reviewing the general condition of the patient the abdomen is examined at intervals during labour in a manner similar to that described for the ante-natal period, special attention being directed towards the descent of the foetal head and the force of the uterine contractions. Vaginal examination is necessary only immediately after the membranes have ruptured or when descent of the foetal head seems to have been arrested in spite of good contractions after several hours in strong labour. It is advisable to pour a quantity of 1 in 1,000 acriflavine in glycerin into the vagina before introducing the fingers, and only the accoucheur in charge of the case should be allowed to examine. In addition to the particulars observed at the ante-natal examination several further points must receive attention. The presence or absence of oedema of the hypogastrium and vulva, and the state of the vaginal wall—whether normal and moist, or hot, dry, and oedematous—are noticed. The degree of thinning and dilatation of the cervix, the presence or absence of cervical oedema, and the relation of the cervix to the presenting part—whether closely applied or drooping in a skirt-like manner into the vagina—are determined. Special attention is directed to the foetal membranes to decide whether they are intact or ruptured; if they are intact, whether they bulge to a normal or abnormal degree during pains; and if they are ruptured, whether or not a loop of umbilical cord has prolapsed into the vagina. The position and degree of engagement of the presenting part, the amount of moulding, and the size of the caput succedaneum are also defined. These seemingly elementary points can prove of considerable importance in approaching a decision as to future treatment in a difficult case. All findings at each examination should be carefully recorded in order that the progress of labour may be accurately followed.

Termination of Labour

Favourable signs observed during the course of labour are good behaviour on the part of the patient, the occurrence of regular normal uterine contractions, good head flexion, a normally dilating cervix closely applied to the presenting part, absence of cervical oedema, and persistence of the intact bag of waters until the cervix is almost fully dilated.

When the foetal head has entered the pelvic cavity labour may be allowed to proceed, and a normal delivery may be anticipated in the majority of cases. In a certain proportion of cases maternal or foetal distress may become evident, and it may be considered advisable to terminate labour forthwith by a low forceps operation. Evidences of maternal distress upon which reliance is usually placed are deterioration in physical appearance in spite of proper care during labour, with a rising pulse rate and temperature. Foetal distress is usually shown by disordered action of the foetal heart. This may be excessively rapid or abnormally slow, irregular in rhythm or variable in rate. A foetal heart rate, previously normal, rising to over 160 beats or falling below 120 beats per minute, an irregular rhythm, or a heart rate rising steadily and then

falling in a comparatively short time, even though still within normal limits, is suggestive of foetal hazard. The timing of the delivery necessitates careful judgment, as extraction may be more difficult if performed too soon and may therefore endanger the life of the child and increase the risk of damage to the mother, while delay may result in intra-uterine death of the foetus. If in doubt timely application of the forceps, in the absence of contraindications, and slow extraction are the best principles to follow. The child must be treated with great gentleness both during and after delivery (Hunter, 1937a). Rapid delivery may precipitate death in a distressed foetus. Episiotomy is performed, when necessary, by an L-shaped incision of the perineum, which must be carefully sutured in layers after delivery. Adequate time should be allowed for placental separation during the third stage.

In a minority of cases it is necessary to terminate labour by Caesarean section, the trial being considered to have demonstrated delivery per vaginam to be impracticable. Lack of advance of the foetal head in spite of satisfactory contractions an hour or more after rupture of the membranes, excessive moulding and caput formation without progress, and early evidences of obstructed labour are usual indications; and signs of maternal or foetal distress becoming evident while the greatest diameter of the foetal head remains above the pelvic brim sometimes hasten the decision to deliver by way of the abdomen. Relative indications also include increasing oedema of the cervix and lack of intelligent co-operation on the part of the patient. Lower segment Caesarean section is the procedure of choice, but in rare cases, if this is rendered more than usually difficult by oedema of the bladder wall, hypogastric oedema, or excessive vascularity of the lower uterine segment, it may be necessary to substitute the classical operation (Hunter, 1937b). Operations involving destruction of the foetus have no place in the management of properly conducted cases of trial labour.

While the above instructions have been expressed in a dogmatic manner for the sake of clarity, it must be appreciated that a certain amount of elasticity must be allowed in dealing with cases of this class, a great deal depending upon the personal judgment of the obstetrician concerned.

Management of Subsequent Confinements

Certain conclusions may be drawn from a completed trial labour. It may be considered that normal delivery may be anticipated in future if the labour has terminated satisfactorily, but it must be borne in mind that in multiparous patients the foetus tends to get bigger with subsequent pregnancies, and the patient should therefore be examined afresh on each occasion. If difficulty of a moderate degree has been encountered it may be decided that induction of premature labour will be necessary in any subsequent pregnancy. When greater difficulty has arisen, especially if Caesarean section has proved to be necessary, it will probably be decided that this operation should be performed before the onset of labour on future occasions.

Summary

Trial labour is a conservative procedure, the employment of which is justified by the element of doubt existing primarily as to the efficiency of the uterus before labour has begun.

The procedure is applicable to cases in which, although a moderate degree of disproportion is present, delivery per vaginam without undue damage to mother or child

is thought to be possible, provided that complications do not arise during labour.

The selection of cases for trial and the management of labour are of first importance. A suggested routine is described.

The decision as to the management of future confinements may be based upon the experience gained from a trial labour.

ACUTE ANTERIOR POLIOMYELITIS FOUR SIMULTANEOUS CASES IN A SCHOOL

BY

G. O. BARBER, M.A., M.B., B.Ch.

The occurrence of four simultaneous cases of anterior poliomyelitis in a boys' boarding school has afforded an interesting opportunity for inquiry into the possible method of infection, and the evidence suggests a route which might be worthy of further experimental investigation.

History of the Outbreak

On July 15 four boys were admitted to the sanatorium from the same house for different groups of symptoms, which are given below in detail in each case history. No boy seemed really ill, and all were put to bed for observation. By the next morning it seemed evident that they bore a major resemblance to one another, each suggesting a more or less severe disturbance of the central nervous system in its earliest stage. A fifth case was admitted as suspicious, but it was soon seen that no physical signs were present. There was sufficient justification to call in expert advice, and the four boys were seen that afternoon by Sir Charles Wilson and Drs. Camps and Maclean, who confirmed a provisional diagnosis of acute anterior poliomyelitis. Lumbar puncture was done on three of the cases. On July 17 three of the boys showed definite signs of paralysis of more than one group of muscles; the fourth showed definite weakness in one muscle of the arm only, and continued alteration of the abdominal reflexes. The fifth was definitely settled as negative.

On July 22 Dr. Brinton saw the four cases after paralysis had set in, and assessed the amount of paralysis in each case. Further details of the cases are supplied in the table.

Shortly after the notification of these cases information was received that six others had occurred during the previous fortnight in villages about ten miles away, on the opposite side of Braintree. During the subsequent eight weeks cases were notified scattered throughout the district of Essex surrounding Braintree, which is the largest town in the neighbourhood. But there were many villages and small towns within the area which were without a case. The accompanying chart shows all cases on the days of their first development, and their distances from Braintree, where the largest number of cases eventually occurred.

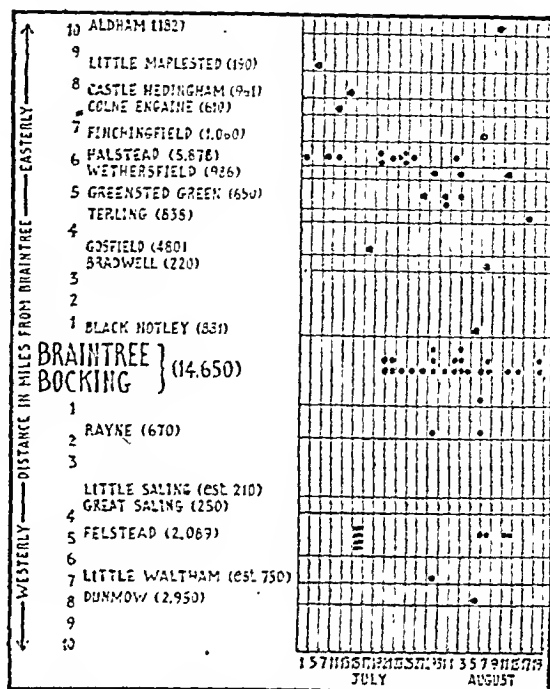

CHART 1.—Date of onset of cases occurring in Braintree and the surrounding district. (The figures in parentheses refer to the population.)

Possible Sources of Infection to the Four Schoolboys

As the four cases in the school all occurred on the same day, and none are recognized as having occurred there before or afterwards, a close analysis was made of the daily habits and lives of these four boys in order to discover any factors common to all four which would point to the source of infection. It certainly appears unlikely that the presence of a carrier in the house was the explanation, as one would then expect a series of cases at intervals rather than such an isolated batch. But it is important to note that cases did appear later in the village, and that two of them occurred in the family of one of the maids employed by and living in the house. These cases were attributed to the maid having carried the infection home. As she was in the house for the rest of the term and no further cases occurred there, and as one attempt to infect a monkey from her proved negative, there is no actual evidence in our present state of knowledge that she was in fact a carrier. Analysis shows:

1. All the four cases occurred in the same house of fifty boys. This house has separate feeding arrangements and a separate domestic staff from the rest of the school.

2. Inside the house only two of the boys slept in the same dormitory: these two were quite friendly and sat near each other in the dining-room. The other two were in different dormitories, and each was unconnected with the others in any activity.

3. In the house-room all four were in different corners, and one of them was only present occasionally as a house prefect.

4. In the school all four were well scattered, being in different classes and other categories.

Table showing Particulars of Cases

| | School Details | Previous Symptoms | Symptoms on Admission | Physical Signs on 16/7/38 | Later Physical Signs | Lumbar Puncture | Muscles | |
|---------|---|---|---|---|--|---|--|---|
| | | | | | | | Paralysed | Weak |
| Case 1 | Aged 17. Form VI. Dormitory 3 | Two weeks before dull diffuse headache. One week before felt run down, due to pressure of exams. | Headache. Anorexia. Dizziness. Constriction around chest. Hazy vision | Temp. 103° F. Tongue furred. Nasopharynx injected. Optic fundus congested. Stiff neck; weakness in trunk muscles and dorsiflexors of feet. Reflexes : Pupils react R. > L. Absent abdominals. K.J. very diminished. Plantar flexor weak | Diminished reflexes of upper limbs. Temperature fell to 98.4° in six days; remained normal | Specimen grossly contaminated with blood | | All upper limb muscles including pectorals; Trunk muscles; spinal; rect. abdom. R. & L. Dorsiflexors of glutei and ankles |
| Case 2 | Aged 16. Form IVb. Dormitory 1 | Epistaxis. Vomited one night before | Headache. Anorexia. Dizziness. Stiffness and feeling of weakness in lower limbs and back. Epistaxis | Temperature 101° F. Tongue very furred. Throat dry. Optic fundus congested. Stiff neck, rigid, weakness in sitting up; pain in lumbar muscles; pain on leg movement Reflexes : Pupils react equal. Abdominals : R. lower absent. K.J. : R. only reinforced; L. weak. Plantar flexor weak | Abdominal reflexes disappeared. K.J. absent Temperature rose to 99° at night for three weeks | Clear. No raised pressure. Sugar nil. Lymphocytes increased. Some blood cells | Extensors of knees. Dorsiflexors of ankles | Adduction of shoulders? Diaphragmatic muscles. Other muscles of lower limbs |
| Case 3 | Aged 15. Form IVc. Dormitory 2. In dining-room next Case 4 | One week before fell on head; headache for three days. Three days before sleepless, restless, and shivering | Headache. Anorexia and nausea. Dizziness. Stiffness of neck and feeling of extreme weakness and lassitude | Temperature 102° F. Tongue furred. Stiff neck; pain in back on movement; weakness in sitting up; cramps in legs. Reflexes : Pupils react equal. Abdominals absent. K.J. : R. only when reinforced; L. present. Plantar flexor weak. Kernig's, mild plus | Weakness in arms. Flaccid paralysis of legs. Temperature normal after eight days but rose to 90° F. each night for three weeks | Clear. Pressure plus. Sugar normal. Cells 10 per c.mm. Chlorides 750 mg. per 100 c.cm. Protein 20 mg. per 100 c.cm. | Dorsiflexors of L. wrist. Lower limbs complete (18/7/38) | All upper limb muscles, especially adductors of shoulders and extension of elbows. Diaphragm. Erector spinae. Glutei |
| Case 4 | Aged 15. Form IVa. Dormitory 2. In dining-room sits next Case 3 | Two days before headache after being hit on the head with a cricket ball | Headache. Nausea. Dizziness. Pain in chest on coughing | Temperature 102° F. Tongue furred. Abdominal reflexes absent, except weak lower R. | Absence of deep reflexes of left arms. Absent right biceps jerk (left-handed boy). Left grip and extensors weaker than right. Abdominals back to normal. Temperature normal after five days, but rose intermittently for a fortnight | Lumbar puncture not done | | Left dorsiflexors of wrist and left extensors of elbow |
| Suspect | Aged 15. Form Lower VIa. Dormitory 6 | Headache three days before, with lassitude. Five days before, stiff in arms and legs, after lying on damp grass | No headache or any other symptoms. Pain in chest | Temperature 99° F. Tongue furred. Central nervous system all normal | None. Temperature normal after six days | | | |

Investigation into the Food Supply

The only common factors appeared, therefore, to be as stated above in paragraph 1—namely, the same feeding arrangements and contact with the same domestic staff. So far as can be ascertained there was no occasion when any outside person was in the house in a temporary capacity, save for one "old boy" visitor; and contact with the domestic staff did not vary significantly from day to day so as to cause infection to all four boys on one day only. Speech Day had been held on July 1, when there was a large influx of parents and relations; but here again there was no occasion when this one house only was in contact with one particular outsider or group. The tendency on that day is for the whole school to mix more thoroughly than usual.

The supply of food was investigated as a matter of routine only, as the present ideas of the transmission of the virus point to a nasal route through the cribriform plate and the olfactory bulbs. There are, however, eminent upholders of the gastro-intestinal route (Toomey, 1934; Kling, 1937). And Walshe (1927), in his description of the clinical course of the disease, stresses the fact that in the pre-paralytic stage there are signs of a general

infection with changes in the gastro-intestinal tract and its associated mesenteric glands before the central nervous system shows signs of being affected.

The following are details of the food supply: Milk is supplied to the whole school by the same dairy. Water is from a well in the house; this has been in continuous use for many years. Analysis on August 2, 1938, for what it is worth, showed satisfactory chemical and bacterial purity. Bread is supplied from the same source as the rest of the school. Butter comes from a large store in a neighbouring unaffected town. Fresh fruit and vegetables are obtained from a fruiterer in Braintree who supplies this house only. I happened to remember that the house has an annual treat of strawberries, and on inquiry I found that this occurred on June 27 and 29, and that the strawberries came from two farms, one of them at Halstead.

Here was a definite connexion with the other area which had been affected from July 1 onwards, and an event that had occurred sixteen and eighteen days before the four cases developed simultaneously in the only house where the strawberries were eaten. But as all the boys in the house had no doubt eaten them, could one reasonably speculate on anything about strawberries which would

pick out four boys only? Strawberries grow very near the earth, and are usually contaminated with it, as well as the common garden pests and their excreta. If it were conceivable for the virus to be present in such contamination, then accident would no doubt account for its being

CHART II.—Curves showing the course of the epidemics of 1916 and 1931 in New York. The similarity of the two is remarkable; note that the highest count in each year occurred on the same day, August 1. (Reproduced by courtesy of the New York City Department of Health.)

CHART III.—Seasonal distribution of infantile paralysis in different climates. Northern and Southern States, 1912-27; intermediate States, 1913-27; Australia and New Zealand, June, 1924, to August, 1927. (From Aycock, *Journal of Preventive Medicine*, 1929, 3, 245.)

ingested by a small number only of those eating the fruit. The simultaneous onset certainly resembles a food-poisoning outbreak rather than an epidemic spread by droplet infection.

Resemblance to Food Poisoning

This line of thought, though apparently far-fetched, could not be lightly dismissed when one considers how easily it would explain the majority of the well-known puzzling features in the epidemiology of the disease—namely:

1. The marked seasonal and climatic incidence (see accompanying graphs from the New York Health Bureau) agrees closely with the seasonal increase in the consumption of fresh garden produce and its climatic maximum production.

2. The epidemiological distribution of the disease does not resemble that of respiratory infections; it resembles that of food-poisoning and typhoid.

3. It is definitely *not* highly infectious. Until recently, cases were nursed from the start in general wards of general hospitals, and there have been no well-authenticated cases of infection to contacts. Certain of the cases in this recent outbreak occurred in crowded families, and were not reported until the illness had been in the paralytic stage for several days. During this time other children had been sleeping every night in the same bed as the paralysed child, and in no case was one of these contacts affected later.

4. The virus is said to be recoverable from the faeces of patients, proving that it is present in the alimentary canal.

5. In the classical case recorded by Draper a carrier was definitely postulated from the evidence as being a Greek fruiterer. All the cases were in contact with him as business associates, relations, or customers, and there is nothing in the evidence to point to the infection being carried by the man himself other than by the fruit he supplied.

This possible route of infection has already been discussed by Kling in Sweden on rather different evidence. The present account is given with the object of suggesting to virus workers a line of investigation that might be worth pursuing. It might then be thought worth while to experiment, for example, on passing the virus through some of the many possible contaminants of fresh garden produce—namely, earthworms, slugs, snails, insects, frogs, birds, and domestic animals and their excreta—or at least to determine the period of survival of the virus in fruit and vegetables.

Should anything of value result it would of course point the way to the prevention of the disease, as well as cause a radical alteration in the present attitude towards isolation and quarantine.

Summary

The history of an outbreak of anterior poliomyelitis in a boys' boarding school is recorded, with details of cases.

An account is given of an investigation into the cause of the epidemic.

The simultaneous onset resembled a food-poisoning outbreak, and is discussed from this aspect.

A line of investigation is suggested to virus workers.

Charts II and III are reproduced from Dr. George Draper's *Infantile Paralysis*, published by the D. Appleton-Century Co.

RAPID PRODUCTION OF AUTOGENOUS VACCINE FOR TREATMENT OF PNEUMONIA WITH NOTES ON ITS USE

BY

F. P. G. de SMIDT, M.R.C.S., L.R.C.P., D.P.H.

*Late Director of the Bacteriological Section, Medical Research
Laboratories, Kenya*

As the result of an investigation into the type constitution of pneumonia in Kenya during the years 1930 to 1935 a striking preponderance of infections due to the "Group IV" pneumococci over the standard American Types I, II, and III was observed; and this appeared to be the rule in lobar pneumonia among European and Indian residents as well as among African natives. The following table shows the results of typing a series of 776 cases of lobar pneumonia, mainly among natives, the figures including a small proportion of cases of pneumococcal meningitis, in which the commonest causative organism was Type I:

| | | | | |
|----------------------|-------|------|------|----------|
| Pneumococcus type .. | I | II | III | Group IV |
| Type incidence .. | 22.0% | 5.6% | 8.3% | 64.1% |

Serological analysis of the Kenya Group IV, begun in 1931, produced twenty-one distinct types up to October, 1935, when I was obliged to retire from work. While the majority of the very severe and fatal cases of the series were due to Type I, many were attributable to the Group IV pneumococci, of which the Kenya types designated as Kw.D, Kw.J, Kw.L, Kw.M, Kw.O, and Kw.V were found to be especially important. It is of interest that some of these were identified with types of the American series. But this picture suggested that the most rational means of specific biological treatment of pneumonia, where the causative pneumococci were so largely diverse, should be found in vaccine made from the actual infecting type cultivated from the patient to be treated.

The Case for Vaccine Treatment of Pneumonia

It cannot reasonably be doubted that lobar pneumonia is essentially a localized infection for which vaccine treatment is well suited, provided that, whatever the vaccine chosen, it is used in a sufficiently early stage of the attack—preferably within the first forty-eight hours. In this connexion W. H. Wynn (1934) says: "When the patient is seen within the first three days a vaccine or serum should be given. A vaccine has the great advantage that it is immediately available." The point here in regard to the immediate availability of the vaccine is, of course, that no preliminary typing of the patient's pneumonia is needed as for serum treatment. The vaccine Wynn uses "contains equal numbers of pneumococci, streptococci, and *B. influenzae* (P.S.I. vaccine)." The dose for an adult is "200 millions of each organism—that is, 600 millions in all"—and the object of the vaccine is "to stimulate the production of non-specific antibodies in adequate amount; the specific effect is not seen for some days." The only criticism I offer is the obvious one that the patient's infecting type of organism might not be represented in the vaccine bottle, so that no specific effect might follow at all. Reliance is therefore evidently placed mainly on the non-specific stimulus of the vaccine employed. If the vaccine used is an autogenous one, the specific effect can be looked for with certainty, and may play an extremely valuable part.

It has been urged against the principle of vaccine treatment of pneumonia that, since antibodies are already present, injection of vaccine is likely to induce a dangerous "negative phase." Here it is presumed, apparently, that antibodies are already present in adequate amount, though such could hardly be the case in a severe illness. And when the clinical signs indicate that the antibody concentration is below that needed for victory over the infecting antigen, the question to be answered is if it is legitimate to risk by vaccine injection this postulated "negative phase" with a mind to its being followed speedily by an abnormal rise in the antibody concentration and a consequent improvement in the condition of a patient who otherwise is likely to die—or, at least, to undergo a very distressing illness which might be cut short by the vaccine. As a result of my experience in vaccine therapy I regard the "negative phase" as a boggy from the pedantry of which a modern pathological outlook seems largely to have freed itself: in every case treated by means of specific or autogenous vaccine I look for an immediate "non-specific" effect in stimulation of antibodies, and doubtless my experience in this matter is shared by others.

With regard to the use of chemical substances in treatment of pneumonia, the following quotations from a letter by Alexander Fleming (1938) are apposite. In reference to the results of his experiments with "T 693" he writes, "I have come to the conclusion that chemotherapy and immunotherapy in pneumococcal infections are not competitive but complementary." He says, also, that "the more immune the patient is the better will be the killing of the pneumococci, and the ultimate result will depend on whether the patient has sufficient resistance to deal with the pneumococci even after they have been in contact with the drug." Further, he continues, "Pneumonia is a serious disease, and should be treated by all methods which have the effect of increasing the immunity of the patient or which are detrimental to the pneumococcus." And to quote from this valuable communication again, the writer says: "We must not forget that it is possible to immunize patients actively by means of vaccines. It has been shown that in animals which have received pneumococcal vaccine protective antibodies can be demonstrated within three days, and the same thing has been demonstrated in patients suffering from pneumonia." The foregoing is a useful corrective to that sceptical attitude which is met with too often in regard to vaccine treatment of pneumonia—an arbitrary scepticism not founded on any special knowledge and experience. There is no doubt that in Kenya many people die of pneumonia whose lives might have been saved by vaccine, and doubtless this is true elsewhere.

Preparation of "M.P.W." Autogenous Pneumococcal Vaccine

The obvious disadvantage of an autogenous vaccine for pneumonia, where vaccine injections must be begun in the earliest possible stage of the illness, is the length of time taken to prepare it by even the most rapid and certain ordinary methods. The procedure below described for the preparation of autogenous pneumococcus vaccine, designated as "M.P.W." vaccine, which consists of the rather obvious expedient of washing out the peritoneal cavity of a sputum-inoculated mouse and using the heavy pure suspension of pneumococci thus obtained as vaccine, enables injections of it to be made on the morning following the day or evening on which the first specimen of the patient's sputum is collected, thus securing a very impor-

tant saving of time. It only rarely happens that a satisfactory specimen of sputum cannot be obtained in the first two days of a pneumonia attack. It may be objected that a mouse inoculated intraperitoneally with an emulsion of genuine pneumonia sputum may produce cultures of casual pneumococci that have come to adhere to the sputum during its rapid transit of the upper respiratory passages and throat. This objection is scarcely valid or warrantable by experience: the infecting type of pneumococcus being extremely abundant in the sputum and of maximum virulence for mice, the chance that a mouse would, so to speak, ignore these in favour of a few adventitious pneumococci must be negligible.

TECHNIQUE OF PREPARATION

The procedure adopted for making M.P.W. vaccine is as follows:

1. Inoculate a large mouse, or preferably two mice in case of accident, intraperitoneally with 0.5 c.cm. of a rather thick saline emulsion of a satisfactory specimen of pneumonia sputum. The specimen should have been collected direct into a sterile tube from the patient's mouth. There is no need for preliminary washing of the specimen.

2. The mouse should be chloroformed when moribund rather than be allowed to die. It is then pinned out on a board that immediately before has been dipped in a strong solution of disinfectant, and the whole of its anterior surface painted liberally with iodine. The skin is deflected, and the exposed surface of the abdominal wall painted with iodine again before opening the peritoneal cavity. Before each stage of the dissection the scissors and forceps are dipped in spirit, which is flamed off.

3. A smear is made of the peritoneal exudate and Gram-stained to verify pneumococcus culture of normal abundance. With a sterile wool-plugged pipette and test the peritoneal cavity is then first washed into about 1 c.cm. of plain saline, giving a dense suspension which may be used if desired for bile-solubility tests or agglutination tests with standard type sera. But this preliminary wash may be dispensed with.

4. The main peritoneal wash for the vaccine is then made into about 4 c.cm. of 0.5 per cent. phenol saline in a sterile wool-plugged centrifuge tube. This is suitably closed or covered (I use a cut-off segment of a rubber stopper, sterilized by flaming) and spun at about 6,000 revolutions for thirty seconds to throw down cells and flocculi.

5. The supernatant pneumococcus suspension is pipetted off into a wool-plugged tube, which is then covered with a rubber cap and immersed up to the cap in a water bath at 60° C. for thirty minutes.

6. The killed suspension is then introduced into a small vaccine bottle, labelled with the dose to be given. This is 1,000 millions of cocci, generally contained in an injection volume of 0.5 c.cm. The vaccine is administered to the patient immediately after bottling; the usual tests of its sterility may be safely dispensed with.

A full-grown mouse generally yields 4 to 5 c.cm. of suspension of a density of 1,000 to 3,000 millions per c.cm., corresponding to opacity representing from 0.3 to 0.6 mg. Burroughs Wellcome's opacity tube scale was used for estimating the strength of these vaccine suspensions; to obtain the value in millions the mean was taken of the two correlations with Wright's and the haemometer methods of estimation. The dose in cubic centimetres of the vaccine is, of course, adjusted according to the strength of the suspension obtained from the mouse peritoneal wash. A too heavy suspension should be diluted with carbol saline so that between 1,000 millions and 1,500 millions of cocci may be contained in a convenient volume for injection of about 0.3 to 0.5 c.cm. It is preferable that the vaccine should be considerably over the strength of 1,000 millions; the extremely low toxicity of killed pneumococcus suspension should be borne in mind.

Dosage of M.P.W. Vaccine, and Therapeutic Trials

This type of vaccine was first produced and experimented with by me seven years ago, with the clinical collaboration of Dr. P. C. C. Garnham (1931) of the East African Medical Service, in a series of cases of pneumonia exclusively among natives. Two factors here militated against success: one was that natives with pneumonia seldom come to hospital until their illness is in an unfavourably late stage for vaccine treatment; the other was that the dosage then employed—only 100 millions of pneumococci—was far too low to be likely to be effective with patients in such circumstances. The only apparent effect of the vaccine in these first trials was a slight reduction of the average duration of the febrile period from about eleven days to about nine days (pneumonia in Kenya is apt to be remarkable for the long period between onset and crisis).

It became evident that the best opportunities for testing the vaccine method would be afforded by European patients, who were more commonly under medical care in the earlier phases of their pneumonia. Accordingly in 1933 further trials were made with this vaccine in heavier dosage, in the first instance with a European severely ill with lobar pneumonia, the sputum yielding the Kenya Group IV type Kw.D (Type VIII of the American series), from which M.P.W. vaccine was produced containing 400 millions per c.cm. Encouraged by the obvious success of the vaccine in inducing an early crisis in this case and by the absence of toxic reaction to the injections, trials were made with higher dosage on native cases of pneumonia, more with a view to acquiring further experience of tolerance than in the hope of good therapeutic results with patients who, as has been said, come for admission to hospital in unfavourably late stages of the attack. Doses up to 3,000 millions were thus tested. No definite evidence of toxic reactions to such dosage appeared. Therapeutically the results were variable: sometimes the desired effect of a pronounced fall of temperature or early crisis on the day following injection was secured, but more often results were indefinite—this generally with patients whose treatment had to be begun too late. To test the vaccine with early cases among Europeans it was necessary to win by slow degrees the confidence and interest of the local practitioners in this method of treating pneumonia. Consequently, the number of European cases treated early in the disease with properly high dosage of M.P.W. vaccine had only reached the very inadequate total of eight before I was obliged to discontinue work finally in 1935. Brief details of these cases and one native case are given below, partly for their interest, but largely in the hope that some of the many pathologists whose laboratories are attached to a general hospital may be induced to give the method a searching test in the medical wards.

Illustrative Cases

Case 1.—A middle-aged male European, two days ill with lobar pneumonia. Cardiac and respiratory embarrassment was very marked. M.P.W. vaccine was given at midday. Six hours later there was a very slight rise in the temperature, and the patient said he felt as though a cold in the head were coming on. The next day he was more comfortable, and had greatly improved in the evening. The following morning the temperature had fallen by crisis, and the patient said he felt well. A second injection was given three days after the first, and a third injection after another three days. Convalescence was rapid and uneventful from the day of the crisis. The nursing sister in charge said she had never seen a severe case of pneumonia get well so quickly. The infecting organism

was the Kenya Group IV type Kw.D. (Type VIII of the American series).

Case 2.—An elderly male European with lobar pneumonia; severe Type II infection. M.P.W. vaccine was given on the third day of illness. The temperature was 101.5° the same evening but dropped to 97.5° at 6 o'clock the next morning, the patient feeling better and being less cyanosed; the temperature rose to 99.6° the same evening. Vaccine was given again the following day, when the temperature was subnormal. Convalescence was regular from that date. The doctor in charge of the patient wrote, "One of the most successful cases of lobar pneumonia I ever had."

Case 3.—A female European with lobar pneumonia; severe Type III infection. M.P.W. vaccine was given late in the illness. The only notes available are the doctor's report that it was a good case and the patient made a quick recovery, the crisis occurring forty hours after the vaccine injection.

Case 4.—A female European with lobar pneumonia; extremely severe Type I infection. M.P.W. vaccine was given—2,000 millions. The patient was said by the doctor in charge to be moribund when the first injection of vaccine was made, and he regarded this as the last hope. The next morning her condition was reported satisfactory. A second injection was given forty-eight hours after the first, and the crisis occurred within the next twenty-four hours. The doctor said that the vaccine "worked a miracle for the patient."

Case 5.—A male African with lobar pneumonia; severe infecting pneumococcus type "Kw.S." The mouse peritoneal exudate from which the vaccine was made included also a strain of Friedländer's bacillus, in numbers exceeded by the pneumococci, so that the vaccine necessarily contained both types of organism. M.P.W. vaccine was given; there was no toxic reaction. Crisis occurred the following day and convalescence was easy. This native case is included here because it was the only one in which a mixed vaccine was used, and it is typical of the few satisfactory native cases that were collected.

Case 6.—An elderly male European who had lobar pneumonia, Type I infection, which proved fatal. He was given 0.08 mg. of M.P.W. vaccine. The only report received on this case was that the vaccine had "no effects."

Case 7.—An elderly male European suffering from a second attack of pneumonia, Type I infection, which ended fatally. M.P.W. vaccine was injected on the fourth day of the illness, the doctor first seeing him on the third day. His temperature dropped to normal about thirty-six hours after injection and the pulse to 106, and he appeared much less toxic. The temperature rose again, however, after a few hours, and he died four days later. Only one dose of the vaccine was given; if it had been repeated the illness might perhaps have run a different course. The vaccine was reported to have had no apparent effect in increasing the toxæmia, but to have been followed by a temporary improvement in the patient's general condition.

Case 8.—A European woman with very severe lobar pneumonia, Type I infection, ending in death. M.P.W. vaccine, 3,000 millions, was given. The temperature fell to 99° the day following injection, but rose again, and the patient died about eighty-four hours later. Only one dose of the vaccine was given by the doctor, but it seemed that this effected a temporary improvement, and should have been repeated.

Case 9.—A male European aged 46, with lobar pneumonia which was extremely severe and involved both lungs. The infecting pneumococcus was a type of Group IV, unclassified. M.P.W. vaccine, 1,000 millions, was first injected about forty-eight hours after onset. During the next two days the patient appeared to be moribund; the Arneil count showed a marked shift to the left, the second lung became involved, and the doctor in charge was nervous of giving another injection of the vaccine. He was encouraged, however, to try a second dose of 1,000 millions, seventy-two hours after the first. The next day there was general improvement in the patient's condition, speedily followed by the crisis, and he made a good recovery.

Scheme of Dosage

It is recommended that the injection be repeated on the following day if the first dose of vaccine has not lowered the temperature by that time; in cases where a good effect had resulted within about thirty hours after the first injection the vaccine might be repeated after forty-eight hours, and subsequently, if thought advisable, at intervals increasing from forty-eight hours to seventy-two, ninety-six, and one hundred and twenty hours. The vaccine should be repeated even when the patient's condition is worse on the day following the first dose: there need be no fear of increasing the toxæmia. It is noteworthy that in the handbook of the South African Institute for Medical Research the dose of 8,000 millions of Lister's prophylactic group pneumococcal vaccine is advised for treatment of pneumonia; and experiments in treatment with the same dose of a similar prophylactic vaccine issued in 1934 showed that the 8,000 millions were well tolerated by pneumonia patients.

Summary

An account is given of the types of pneumococcus found in lobar pneumonia cases in Kenya.

A case is stated for vaccine treatment of pneumonia.

A method for the rapid production of autogenous pneumococcus vaccine ("M.P.W.") is presented.

Details of nine cases of pneumonia treated with M.P.W. vaccine are appended.

AND

G. I. H. BRAINE, M.B., D.T.M.&H.

Colonial Medical Service

Of the 102 cases of gonococcal infection included in this preliminary report, seventy-nine were in men, nineteen in women, and four in young girls. No adjuvant treatment—for example, irrigations—that might be of material assistance was given during the use of the drug under consideration—M & B 693. The results indicate a high proportion of apparent cures (over 91 per cent.).

Toxic effects were encountered in 29 per cent., and their nature and incidence are given later in tabular form. The commonest manifestations of intolerance were nausea and headache, and in most cases these symptoms were slight and the patients were able to continue with the drug in reduced dosage. The discontinuance of the drug was quickly followed by the subsidence of all the undesirable symptoms, and no prolonged ill effects were observed.

In the successful male cases clinical cure was attained in under a week. In the successful female cases signs which might be interpreted as denoting infection persisted for two weeks, but gonococci disappeared from the smears almost as quickly as in the male cases (under three days). Thus in the early cases the gonococcal infection was cured before the time when the disabling complications—for example, epididymitis or salpingitis—are to be expected. Also, cure was effected without the time-consuming and often badly applied local irrigation treatment which was such a prominent feature of the old therapeutic regime. In the future the nightmare of stricture of the urethra, with its ever-present threat of retention or extravasation of urine, should cease to disturb the slumbers of these males whose weakness is sexual indiscretion, and the depressing picture of the chronic pelvic invalid should be less often encountered among the habitués of spas and health resorts.

Above all, the possibility of spread of the disease should be greatly reduced through the shortening of the period of infectivity. There is, therefore every likelihood of a progressive diminution in the incidence of gonorrhoea, and designers of venereal disease clinics will plan on less spacious lines, especially in the accommodation required for irrigation treatment.

Standard of Cure

The standard of cure aimed at, but at the time of assessment not achieved in all the cases quoted, was as follows:

All cases are observed for a minimum of three and a half months to exclude the possibility of superadded syphilis.

Male cases are under observation for at least a month after the cessation of all treatment, and during this time, in addition to the absence of discharge and the maintenance of clear urine, repeated smears of the urethral, prostatic, and seminal vesicular secretions must be free from pathogenic organisms and relatively free from pus cells. These smears must also remain pus-free and organism-free forty-eight hours after a provocative intramuscular injection of 300 to 500 million organisms in a polyvalent gonococcal vaccine. The gonococcal complement-fixation test of the blood must be observed to remain negative or become negative during the period of observation. Instrumental investigation, including urethroscopy, must show a return of the urethral lining to normal.

Female cases are observed for three months after cessation of treatment, and during this time, in addition to the absence of discharge, repeated smears of the urethral, Bartholinian, and cervical canal secretions must be free from pathogenic organisms, especially immediately after the menstrual periods, and also forty-eight hours after the injection of 300 millions of the provocative polyvalent gonococcal vaccine. The gonococcal complement-fixation test of the blood must remain negative or must become negative, and careful bimanual examination must exclude any residua in the uterus or tubes.

Cases claimed as "apparent cures" include some who have not been observed for the minimum periods stated above. In all cases smears were examined very frequently, often daily at first, and the presence of any discharge or other sign of inflammation and the condition of the urine were noted.

Male Adult Cases

ACUTE ANTERIOR URETHRITIS (49 CASES)

The average daily dose was 3 grammes maintained for an average of about five days, and this was followed in

some cases by a reduced dose for a maximum of seven to nine days.

There was apparent cure in forty-three cases, and apparent or possible failure in six cases. In the apparent cures, clinical signs disappeared in under four days (average), and gonococci were absent in smears after two days (average). In the apparent failures, in three cases gonococci were present in smears after the course of drug treatment; of these one received 16 grammes in four days; in the second case treatment was very irregular. 12 grammes being taken in eight days as follows—3, 0, 0, 3, 3, 0, 0, 3. The third case relapsed, and gonococci reappeared in the smears one week after the first course of 15 grammes, but the discharge and the gonococci disappeared quickly on beginning a second course. Two other cases had a return of discharge after 16 grammes in five days, but no gonococci were found in smears; in another case a slight mucoid discharge showing no gonococci in smears persisted after six days of drug treatment.

SUBACUTE GONORRHOEA (ANTERIOR URETHRITIS): 5 CASES

In all these five cases clinical cure was attained in an average of just over four days. A peri-urethral abscess and a sinus discharging gonococcal pus cleared up within a week.

ACUTE, SUBACUTE, AND CHRONIC ANTERIOR AND POSTERIOR URETHRITIS (25 CASES)

In twenty-one of the cases there were complications such as prostatitis, seminal vesiculitis, epididymitis, arthritis, and iritis. In all these cases the urethral discharge cleared up in just over five days and all the complications improved rapidly, including the cases of prostatitis (one with sciatica), arthritis, and even the iritis.

PREVIOUS TREATMENT WITH DRUGS OF THE SULPHANILAMIDE CLASS

Three of the male cases had relapsed after treatment with uleron, one having received two courses each of 20 grammes; the other two had received 16 grammes and 13½ grammes respectively. In the last of these three cases irrigation had also failed, and was stopped when M & B 693 was started. Two of the three cases which had previously received uleron showed toxic symptoms with M & B 693.

Fifteen cases had been treated with sulphanilamide: of these cases thirteen which showed gonococci in smears were clinically cured in five days; one case relapsed after M & B 693, and gonococci reappeared in smears. Two cases developed jaundice after sulphanilamide therapy followed by M & B 693—one twenty-five days, the other twenty-seven days, after receiving the "693."

Two cases had no toxic manifestations with M & B 693 after having had such symptoms as headache, dizziness, and skin eruption while on sulphanilamide, but the dosage of the latter drug was twice that of the "693."

Female Adult Cases

NORMAL DOSAGE (19 CASES)

In seventeen cases the average dose was 2 grammes daily for just over six days, and the other two each received 3 grammes daily for five days. No local treatment was applied other than sitz baths and powdering of the vulva.

Therapeutic Effect.—In sixteen cases gonococci were absent from smears in under three days. Clinical signs such as discharges persisted on the average up to fourteen days. There was only one case of relapse with reappearance of gonococci in the smears, and two cases defaulted.

INTENSIVE DOSAGE

After the initial dose of $\frac{1}{2}$ gramme four-hourly, four cases received four-hourly doses of 2 grammes, 2 grammes, 1 gramme continued, and finally tapering off to $\frac{1}{2}$ gramme in a manner similar to the procedure recommended for cases of pneumonia, the total duration of treatment averaging eight and a half days. In these cases the gonococcus was not found in smears after an average of two days. No relapses were noted during the period of observation. All the cases on intensive dosage developed severe nausea, violent vomiting, and prostration on the first day, although they had tolerated the initial dose of half a gramme.

Toxic Effects on Normal Dosage

Toxic effects were observed in twenty of the seventy-nine male adult cases and in seven of the nineteen adult females. The symptoms, although slight in the majority, were severe enough to necessitate withdrawal of M & B 693 in eight cases (three men and five women), but not before the drug had been given for an average of six days, a sufficient period for it to exert the usual favourable influence on the gonorrhoea. The skin rashes were blotchy, erythematous or papular, and morbilliform in type, affecting the hands, arms (forearms especially), legs (thighs especially), abdomen, and back. The face was not in-

TABLE I.—Showing the Nature and Incidence of Toxic Symptoms in Patients on Normal Dosage

| Nature of the Toxic Effect | Incidence in | |
|------------------------------|--------------|-------|
| | Men | Women |
| Headache | 8 | 2 |
| Nausea | 6 | 2 |
| Dizziness | 3 | — |
| Skin eruption | 2 | 4 |
| Lassitude | 2 | 2 |
| Cyanosis | 2 | — |
| Vomiting | 1 | 1 |
| Breathlessness | 1 | — |
| Diarrhoea | 1 | — |
| Emptiness and hunger | 1 | — |

volved in the most severe eruption seen. There were no cases of photosensitivity in which the eruption is confined to the exposed parts—face, neck, hands, and forearms—although this type of rash has been found in cases treated with sulphanilamide.

The nature and incidence of the toxic symptoms in patients on normal dosage are shown in Table I, some patients exhibiting more than one symptom. All the toxic effects subsided quickly on withdrawal of the drug. One woman felt sick with six tablets (3 grammes) daily, but tolerated four tablets a day. One woman had sickness and lassitude with more than three tablets daily for four days, but nevertheless showed a very good clinical response.

Children with Gonococcal Vulvovaginitis (4 Cases)

These cases received no adjuvant treatment other than sitz baths and powdering of the vulva, with one exception in which menformon was given by injection and orally for two days before the drug treatment was started. As they are of special interest a synopsis of their clinical history is given in Table II.

Management of a Case

There is no necessity to wait for immunity to develop; M and B 693 should be used as soon as the diagnosis is made. The technique suggested by our experience is as follows:

Men should receive six $\frac{1}{2}$ -gramme tablets a day for five days—two tablets thrice daily after food, or, alternatively, two after breakfast, one after lunch, one after tea, and two after dinner or supper. After five days the dose should be reduced to three tablets, or at most four tablets, a day, continued for another five to nine days. The majority are cured by the first five days' treatment.

Women should receive four $\frac{1}{2}$ -gramme tablets daily for five days—one tablet after each of the principal meals, or as follows: one tablet after breakfast, half a tablet at noon, half a tablet at 3 p.m., half a tablet at 6 p.m., and one and a half tablets at bedtime. After the first five days the dose should be reduced to three tablets a day, and be maintained at this level for another five days.

Girls with vulvovaginitis should receive, for the first five days, half a tablet from four to six times daily, according to age, and thereafter, for the next five days, half a tablet thrice daily.

TABLE II.—Clinical History of 4 Cases of Gonococcal Vulvovaginitis in Children

| Case No and Age | Nature of Infection | Number of Days' Treatment till Disappearance of Clinical Signs | Dosage | Relapses | Toxic Effects | Remarks |
|------------------|--|--|--|---|---|--|
| 2747 Aged 5 | Recent acute vulvovaginitis—gonococci present in smears from urethra and vagina | 2 | 0.25 gm. thrice daily for 5 days | None. Observed for 78 days after first negative smears | None | One injection menformon (25,000 units) and menformon tablets for 2 days before M & B 693 started. But smears still contained gonococci |
| 2779 Aged 5 | Recent acute vulvovaginitis; gonococci present in smears from urethra and vagina | 3 | 1 gm. daily for 5 days ($\frac{1}{2}$ tablet every 6 hours) | None. Observed for 30 days after first negative smears | Neutrophil polymorphs reduced from 64% to 41% | At start of treatment white blood corpuscles 15,000 (neutrophil polymorphs 64%). After 5 days' treatment white blood corpuscles 11,000 (neutrophil polymorphs 41%) |
| 2780 Aged 4 | Recent acute vulvovaginitis; gonococci present in smears from vagina and urethra | 4 | 1st Course: $1\frac{1}{2}$ gm. daily for 5 days ($\frac{1}{2}$ tablet every 4 hours) 2nd Course: $1\frac{1}{2}$ gm. daily for 5 days | On 10th day after starting treatment gonococci in smears, but no clinical signs. No relapse in 15 days after second course | Nausea, vomiting. Dose reduced to $1\frac{1}{2}$ gm. daily | After 5 days white blood corpuscles 6,800 (neutrophil polymorphs 55%) |
| A4602 Aged 10 | Recent acute and severe vulvovaginitis; gonococci present in smear | 5 | 1st Course: 4 gm. daily for 2 days; 2 gm. daily for 2 days; 1 gm. daily for 4 days—given in divided doses 4-hourly. Total 16 gm. 2nd Course: $2\frac{1}{2}$ gm. for 2 days; $1\frac{1}{2}$ gm. for 4 days. Total 10 gm. | On 15th day after starting treatment gonococci reappeared in smears. No relapse 6 weeks after completion of the second course | Nausea on the 2nd day, but was able to continue on the reduced dose | Gonococci absent after 4th day of first course and after 1st day of second course |

The tablets are best taken powdered and in half a tumblerful or more of water. During the drug treatment patients should be warned not to take sulphur-containing foods such as eggs and onions, and, if laxatives are necessary, to use only liquid paraffin or extract of cascara, avoiding especially Epsom salts or liquorice powder.

Conclusions

1. M & B 693 can effect clinical cure within a week in a large majority of cases of gonococcal infection, whether of short or long duration and whether occurring in men or in women.

2. Complications originally present, such as epididymitis, arthritis, or iritis, improved rapidly.

3. In the cases quoted there was complete absence of complications or spread of the disease after the start of the drug therapy.

4. No irrigation or other adjuvant treatments are necessary.

5. Toxic effects may occur in less than one-third of the cases, but where normal dosage is employed these are usually mild, requiring only a reduction of the dose.

6. Toxic symptoms are quickly recovered from, and no lasting ill effects have been encountered.

7. Vulvovaginitis also responds well to M & B 693.

8. Our experience has led us to conclude that M & B 693 is the most potent anti-gonococcal agent available at present.

Summary

A report is given of 102 cases of gonococcal infection treated with M & B 693.

The standard of cure aimed at is discussed, along with the general results of treatment.

The clinical history of four cases of vulvovaginitis in children is detailed.

Points on the management of a case are given.

We are indebted to Messrs. May and Baker for supplies of the drug and to Dr. Robert Forgan for advice and literature.

INTERNATIONAL HOSPITAL ASSOCIATION

Toronto, September, 1939

At a recent meeting of the United Kingdom Council of the International Hospital Association, presided over by Mr. W. McAdam Eccles, M.S., F.R.C.S., chairman, there was received a preliminary but very detailed programme of the sixth Biennial Congress of the I.H.A. to be held at Toronto in September, 1939.

The task of the production of this programme has been in the capable hands of Dr. Malcolm T. MacEachern, President of the I.H.A., and Associate Director of the American College of Surgeons, with the assistance of Dr. Harvey Agnew, Secretary of the Canadian Hospital Council and President-elect of the American Hospital Association. Associated with them have been Dr. William S. Coldwell, chairman of the Congress Committee and assistant medical director of the Canadian Red Cross, and the secretary, Mr. Carl T. Flath. By all concerned with the I.H.A. in Great Britain, in the British Empire, and on the Continent, and above all in Canada and the United States, it is believed that this coming congress will be unique in the annals of international hospital affairs, and will stand to show the co-operation of the whole civilized world in the prevention of and the dealing with disease in the modern manner. Forty study committees will be reporting upon their individual work during the preceding two years, and papers of great interest will be read by many experts during the week of the Congress, September 19 to 23.

All particulars concerning the subjects to be discussed and of the travel arrangements to Toronto and back can be obtained from the joint hon. secretaries of the I.H.A., 17, Bloomsbury Square, London, W.C.1.

Clinical Memoranda

Primary Intussusception of the Appendix

Primary intussusception or inversion of the appendix, without complication, is probably a sufficiently rare curiosity to merit report of a case which came under my care while acting surgeon at Offaly (King's) County Hospital, Tullamore.

CASE REPORT

The patient, a young man aged 20, was admitted to hospital after a severe attack of colicky abdominal pains accompanied by vomiting; the symptoms had been present in lesser degree at intervals over the two preceding days. On admission his temperature was 99° F. and the pulse rate 80. Slight tenderness was elicited on deep palpation of the right iliac fossa. Rigidity was not in evidence, nor was any mass felt.

On the following morning the abdomen was opened through a McBurney incision, but the caecum was not delivered with the ease anticipated, nor was the appendix felt. On enlarging the incision and delivering the caecum the three taenia coli were seen to converge on a tiny dimple into which ran a taut band—the meso-appendix. The appendix was felt as a

FIG. 1.

FIG. 2.

FIG. 1.—The specimen (scale, inches).

FIG. 2.—Cross-section of the specimen (actual size). m.a. = meso-appendix; p. = peritoneum; m.m. = mucous membrane.

sausage-shaped mass fixed at the caput caeci, lying within the caecal cavity. Its size indicated engorgement, and an effort to evert it was quite futile. The meso-appendix was ligated and severed and an intestinal clamp lightly placed across the caput caeci, within which lay the appendix. After packing off, the caecal wall was opened by an incision which ended at the site of inversion, the appendix was delivered, and the incision carried round its base. With the usual toilet, closure of the caecum in two layers, and adequate drainage, the operation was concluded in the ordinary way.

Convalescence was uneventful, and the patient was discharged from hospital after eighteen days by the surgeon, Dr. T. Meagher, who had then resumed duties.

I am indebted to Dr. W. R. O'Farrell, pathologist to the Mater Misericordiae Hospital, for the following report on the specimen: "The specimen is a complete inversion of the vermiform appendix. Section shows a central mass of fatty tissue containing large vessels—the meso-appendix; external to this is the muscular coat and the mucous membrane, which shows in places the subepithelial collections of lymphocytes. The whole mass is congested and inflamed. The inversion is complete, and includes the tip of the appendix."

The usual explanation of the condition—an attempt to extrude a concretion or an enlarged lymphatic follicle—probably holds in this case.

JOHN CORCORAN, M.Ch.,
Surgical Assistant, Mater Misericordiae
Hospital.

Dublin.

Reviews

RETROSPECT AND PROSPECT

Thus We are Men. By Sir Walter Langdon-Brown, M.A., M.D., Hon. LL.D., Hon. D.Sc., F.R.C.P. (Pp. 344; 10s. 6d. net.) London: Kegan Paul, Trench, Trubner and Co. 1938.

Since his retirement from the professorship of physic in his old University Sir Walter Langdon-Brown has spent part of his leisure in revising and collating the addresses he gave to learned societies on subjects covering the borderline of medicine, psychology, and religion. Deeply impressed in his student days by the facts of organic evolution, he is led to apply the same rule to the social development of the individual and of the community. He points out that that cycle of time with his own birth as centre includes such remarkable scientific developments as the statement of evolution and Mendelian heredity, the discovery of the bacterial causes of infections, a new aspect of psychology with ability to understand and determine the influence of early training and environment on the reactions to the trials and work of later life, and the control exercised by the ductless glands through the effects of their products and secretions on the somatic and psychological development.

Through these collected essays runs the thread of the course of social evolution of man as apart from the rest of the animal kingdom—that is, the mental or psychological evolution—though psychology is approached from the physiological side. But the author's point of view is not that of the anthropologist but of the physician; for his interest is not so much in the laboratory as in the essential bedside approach to medicine. Thus after a short discussion of primitive social psychology and the modern conception of how the mind works, he brings forward instances of the lack of adjustment to society, to occupation, and to sex; without this the individual cannot become psychologically adult. Only if he can make suitable adaptations to these three social factors can a man be happy and fit. He may succeed in overcoming his difficulties; if not, neurosis, disease, or degeneracy ensues. A second group of essays, more literary in subject-matter and dealing with instances of maladjustment, illustrates escape from the realities of life and unpleasant duties through fantasy or fugue, and failure to adapt to the problems of sexual maturity; instances are given of double personality among the great, and lesser, authors and playwrights. In an interesting and acute piece of criticism Sir Walter Langdon-Brown shows how authors reveal in their characters or the situations that arise in their novels and plays their own inherent psychological imbalance. It is an easy step to contrast and admire the members of the medical profession who have made their mark in literary circles: Sir Thomas Browne, Harvey with his profoundly significant demonstration of the circulation of the blood, the little-known heroes of plague-stricken villages in mediaeval England, and those outstanding examples of humanistic doctors of modern times, Sir William Osler and Robert Bridges. The author's literary inheritance and wide reading have helped him to dip his own pen in the golden ink.

In his third group of essays Sir Walter Langdon-Brown approaches the borderline of philosophy and religion. Man as he emerged as a thinking animal has been beset by fears. His desire for assurance of his own survival, of his continued sustenance, and of his freedom from

disease has been met in the past by the idea of a god whose special care has been the giving of this assurance; sometimes the apotheosis of a fellow man whose tenure of the office was terminable by the selection or personal prowess of a successor. The first biological stage of a community is held together by taboo and fertility rites. In the second individualities develop, and the religious trend is towards longing for assurance of individual salvation and personal immortality. In the stage of evolution that the human race has now reached there is need for conscious co-operation. Again the god is the expression of the soul's sincere desire, and the worship of the State has emerged. As the individual must attain his manhood balance by fusing his ancestors, the community exists by a working compromise of often antagonistic elements. But there is no static position; evolution demands a flow, though always offering a higher or a lower course. The solution can be found by a method which gives adequate freedom to the individual life within a larger co-ordinated unit. Can we achieve it? Sir Walter Langdon-Brown has more optimism than Sir Thomas Browne, who three centuries ago wrote, "Thus we are men and we know not how."

HEART DISEASE IN PREGNANCY

Heart Disease and Pregnancy. By Crighton Bramwell, M.A., M.D., F.R.C.P., and Edith A. Longson, M.B., Ch.B., D.P.H. With a Foreword by Sir Ewen Maclean, M.D., LL.D., D.Sc., F.R.C.P. (Pp. 194; 57 figures, 39 tables. 8s. 6d. net.) London: Humphrey Milford, Oxford University Press. 1938.

The Heart in Pregnancy. By Julius Jensen, Ph.D., M.R.C.S., L.R.C.P. (Pp. 371; 5 figures, 117 tables. 25s. net.) London: Henry Kimpton. 1938.

The fact that our knowledge of heart disease in pregnancy (which for practical purposes can be considered as rheumatic) has not kept pace with other aspects of cardiology must be attributed to the relatively poor opportunity available for expert and prolonged observation of the condition. A large number of data have now been collected, as shown in the two volumes reviewed herewith, but the manner of presentation suggests that final conclusions cannot yet be drawn from them. The book by Drs. Bramwell and Longson is an admirable and concise statement of their experience based on 350 cases. The first step is to decide on the presence or absence of heart disease in the pregnant woman who has certain symptoms, and this may not be easy, since the effects of pregnancy in the normal woman may produce both symptoms and signs which simulate very closely those of heart disease—for example, shortness of breath, palpitation, fullness of the veins of the neck, rales at the lung bases, and a change in the radiographic silhouette of the heart similar to that of mitral stenosis. Such problems are clearly discussed, and the common physical signs fully described. Auricular fibrillation, which is a serious complication not only because it may itself be a severe handicap but also because it occurs in the advanced stages of rheumatic heart disease, is discussed at length; the mortality in the cases with this arrhythmia was found to be four times that of the whole series. In the final chapters on treatment and prognosis the point is stressed that in pregnancy of more than three months' duration artificial termination is nearly always inadvisable, and that when there is heart failure any interference must always be preceded by adequate medical treatment, while the rules given for prognosis should help to lessen maternal mortality. For information on any of the problems connected with heart disease and pregnancy no better source than this well produced and illustrated book is available.

The Heart in Pregnancy, by Professor Jensen, is a more discursive but less practical work. It is largely a painstaking review of the literature, much of which is contradictory, and suffers from the fact that it is only to a small extent a record of personal observations. As a result the reader is apt to be confused, and has to look carefully for definite guiding principles. For those seeking an account of the literature on the subject the book provides a comprehensive summary, but it will be of less value to the practitioner requiring quick access to principles of treatment.

PRACTICAL MEDICINE

Minor Medical Operations for Senior Medical Students and Recently Qualified Practitioners. By Kenneth Harris, M.A., M.D., F.R.C.P., and Edith Harris, M.B., B.S., D.P.H. (Pp. 198; 41 figures. 7s. 6d. net.) London: H. K. Lewis and Co. 1938.

Drs. Kenneth and Edith Harris have written a short and easily readable book on minor medical operations principally designed for senior medical students and recently qualified practitioners. It is probably more difficult to describe practical procedures than to write a straightforward short textbook of medicine, and the joint authors of the present book have not altogether brought it off. For example, the sections on blood transfusion do not contain all those details which show that the authors are frequently carrying out the procedure and appreciate all the difficulties. (Incidentally the "drip" method of giving blood is not described.) Exploration of the chest is better managed (probably because of the connexion of Dr. Kenneth Harris with the Royal Chest Hospital), but it is unfortunate that in the section on artificial respiration Schafer's method is not put first, as most experts are agreed on its superiority. Again, in view of a recent accident it would have been wiser to recommend removing the lid of the tin of cataplasma kaolin before heating it in boiling water, and the authors do not appear to be aware of the "tip" of spreading vaseline over the area to be poulticed, especially when it is hairy (much more effective than the gauze recommended). These criticisms suggest that the authors have not given quite enough thought to the relative ignorance of the audience whom they are addressing.

A careful revision, and in many places considerable extension, would turn this handy volume into a really valuable guide-book to medical and nursing procedures. Incidentally the title suggests the obvious query as to what the authors consider a *major* medical operation.

DISEASES MASQUERADING AS TUBERCULOSIS

Pseudo-Tuberculosis in Man. By Professor I. Snapper. Lectures given in November, 1937, at the University of London. (Pp. 90; illustrated; 12 plates. Fl. 7.50.) Haarlem: De Erven F. Bohn N.V. 1938.

Most diseases whose aetiology is unknown have been fated to have a tuberculous origin attributed to them, even when this has necessitated crediting the tubercle virus with phases of development or effects as yet unproved. For many years several affections showing nodules with a histological structure somewhat similar to that found in genuine "tubercles" have been regarded as tuberculous, though no tubercle bacilli could be demonstrated in them. Such lesions, especially when localized in the skin, have generally been termed tuberculides. This applies to lupus pernio, first described by Besnier in 1889, and to the multiple benign sarcoids reported by Boeck in 1899. Later it was shown that both these conditions were often accompanied by visceral localizations, Schaumann in 1914 being the first to bring

forward the conception that Boeck's sarcoids (or benign military lupoid) must be considered as the cutaneous localization of a general constitutional disease, really identical with lupus pernio. In the first part of his book Professor Snapper gives an admirable account of this condition (recently called Besnier-Boeck-Schaumann's disease), based on thirteen cases he and Dr. Pompen had the opportunity of studying. In these patients no fewer than thirteen different localizations of the typical nodules were observed, swelling of the hilar gland in the chest being the most constant finding. Lesions of the skin, on the other hand, were not always present. The radiological picture may closely resemble "chronic military tuberculosis." Since the outlook for the patient with Besnier-Boeck's disease is good, its presence may account for some of the cases of so-called "healed" military tuberculosis. Jüngling's syndrome, or osteitis "tuberculosa" cystica multiplex, is merely the localization of the same disease in the fingers and toes. Professor Snapper maintains that there is no evidence that Besnier-Boeck's disease is tuberculous in origin.

The second part of the book gives an equally excellent account of "regional ileitis." Professor Snapper asserts that tuberculosis of the intestine is found only in patients with active tuberculosis of the lungs. In non-tuberculous patients a special ulcerative inflammation of the ileum may be observed (described by Crohn, Ginzburg, and Oppenheimer in 1932). Macroscopically and microscopically many characteristics of tuberculosis are seen, but, again, tubercle bacilli are never discovered in them even when animal inoculation is carried out. Professor Snapper gives a detailed account of six personal cases of this disease.

The production of this volume cannot be too highly praised. The format, the binding, the paper, the printing, and the lay-out all show a lavishness that will be the envy of many authors. The ample illustrations on glazed board are superb. It is a pity, therefore, that the English, though quite good, has not been more thoroughly revised.

HYGIENE AND DISORDERS OF INFANCY

Clinical Paediatrics (The Baby). Edited by W. R. F. Collis, M.A., M.D., F.R.C.P., F.R.C.P.I., D.P.H. With a Foreword by Andrew H. Davidson, M.D., F.R.C.P.I., F.C.O.G. (Pp. 460; 89 figures, 17 plates, 7 tables. 21s. net.) London: W. Heinemann (Medical Books). 1938.

Care of Infants and Children. By Harry Lowenberg, sen., A.M., M.D. (Pp. 300. 10s. 6d.) London: McGraw-Hill Publishing Company. 1938.

Dr. W. R. F. Collis has succeeded in editing a useful and practical volume on *Clinical Paediatrics* in which seventeen of his colleagues in Dublin assist him in presenting the main facts about the hygiene and disorders of infants, especially during the earliest part of infancy. Clearly the book has grown out of the work at the valuable infants' department of the Rotunda Hospital (commended in a foreword by the present Master, Professor A. H. Davidson); and the chapters on the newborn baby, in which Dr. Collis has written most of the sections, show a skilful application of modern knowledge to the special conditions of the neo-natal period. The rest of the book is less original, but contains most that practitioners and students need know about feeding and the common medical and surgical disorders of infants, with chapters on diseases of the eye, ear, nose, and throat. Dr. Collis acknowledges the help of his teachers, but unfortunately manages to get the initials and spelling of their names wrong in several instances. Indeed, as a whole the book shows signs of hasty editing, but this does not detract

from its essential value as a common-sense and practical handbook for those concerned with the care of infants.

Dr. Harry Lowenberg, sen., has written a popular volume on *Care of Infants and Children* which intelligent mothers should find most useful. Nurses and even young medical graduates could also learn a great deal about normal infant and child hygiene from its pages.

SURGERY FOR ESSENTIAL HYPERTENSION

The Surgical Treatment of Hypertension. By George Crile. Edited by Amy Rowland. (Pp. 239; 52 figures, 15 tables. 18s. net.) Philadelphia and London: W. B. Saunders Company. 1938.

Although the surgical treatment of essential hypertension is but a recent development the results which have been published to date do not suggest that a treatment which will give uniformly good results has been found. Dr. Crile in this volume presents the thesis that when the coeliac ganglia are removed there is an increased fall in blood pressure which, too, is more lasting. It is early to say whether or not Dr. Crile's new treatment will be the method of choice in the future, as his first operation was performed on May 6, 1936, and his records only cover a period of about twelve months from the time of operation. It must be admitted that in his hands coeliac ganglionectomy produces a greater fall in blood pressure than does any of the other operative procedures at present in use. One must criticize, only on general principles, an operation which is carried out almost entirely by touch. There does not seem to be any valid reason for this "touch dissection," especially since so many surgeons are acquainted with the methods of coeliac anaesthesia by the transperitoneal route. Some modification of this method to enable it to be used for extirpation of the ganglia seems to present no serious anatomical difficulties, with the added advantages that (a) preliminary anaesthesia of the ganglia might give some idea of the probable result of extirpation on the blood pressure, and (b) all of the structures to be removed could be identified *seriatim* in full view. Dr. Crile develops his argument for the removal of the coeliac plexuses in an interesting way and has added a most complete bibliography and discussion of the literature of the treatment of essential hypertension by surgical methods.

Notes on Books

The thirteenth edition of Osler's *Principles and Practice of Medicine* has been revised by Dr. Henry A. Christian (Appleton, 35s.). Originally brought out in 1892, two years after the first edition of Taylor's *Medicine*, it has run a very similar course, the ninth, tenth, eleventh, and twelfth editions having been produced by Thomas McCrae. From his position as professor of medicine at Harvard and as a pupil of Osler and a friend and colleague of McCrae, the new editor, who is anxious to continue its traditions, will be heartily welcomed by all those who have been educated on this outstanding work. While closely following the inherited characteristics, much—about two hundred pages—new material has been added, and this edition is a worthy successor of its twelve predecessors.

The third volume of the first series of *New International Clinics* (J. B. Lippincott Company; 4 vols., 50s.) contains twenty original articles; a symposium on some of the uses of sulphanilamide, including its employment in the pneumonias, urinary infections, pelvic infections, and diseases of children; clinical lectures on Bright's disease, heart

disease, retroperitoneal meningococcus infection, obesity, and acute hypocyctic lymphatic leukaemia; and a review of recent work on pyelitis in pregnancy. Among the original articles special attention may be drawn to those on clinical and experimental observations on adrenal insufficiency, diabetic acidosis, favourable and unfavourable results from the practice of modern obstetric trends and procedures, present status of the surgical management of peptic ulcer, dermatitis from wearing apparel, urology for the general practitioner, caudal anaesthesia in proctology, and pulmonary tuberculosis and heart disease in anthracosis.

Die natürliche Heilweise im Rahmen der Gesamtmedizin (the place of natural therapy in medicine) contains a series of some thirty lectures by different persons, and is edited by Dr. C. ADAM. The editor explains the general purpose of the volume as follows: "The new German therapy is distinguished by the striving after synthesis. The desire of the Reichsärztesführer is to build into scientific medicine the valuable portions of empirical and folk medicine. This is in accordance with the desires of all well-wishers to the health of the German people." The volume includes articles on many aspects of modern therapy and also articles on homoeopathy, folk medicine, etc. It is published by Gustav Fischer of Jena at RM. 14.

Preparations and Appliances

HEPATEX-T FOR THE TROPICS

Hepatex-T (Tropical), which is manufactured by Evans Sons Lescher and Webb Ltd., is a combination of liver principles intended for the treatment of the nutritional macrocytic anaemias which arise in tropical countries. These anaemias were first recognized as occurring in pregnancy, but have been produced in experimental animals by nutritional deficiencies. The disease was found to be relieved by liver feeding or by crude extracts of liver, but this effect is now known to be due to factors other than anahaemin. An unknown factor, vitamin B₁, and the vitamin B₂ complex all appear to be concerned. The same is more or less true in the case of sprue.

Hepatex-T (Tropical) is a preparation for intramuscular injection (dose 2 c.cm.), which is believed to contain all these factors, which are beneficial in the tropical anaemias mentioned.

CRYSTALLIZED TESTOSTERONE

Sterandryl (Roussel Laboratories, Ltd.), a preparation of crystallized testosterone propionate, is an oily solution intended for intramuscular administration and is supplied in three concentrations: 5, 10, and 25 mg./c.cm.

Investigation of the clinical action of the male sex hormone has been hampered until recently by the difficulty of obtaining adequate quantities, but the synthesis of testosterone has now been achieved. The practical significance of this advance is indicated by the fact that extraction of a quarter of a ton of bulls' testicles would be needed to provide 25 mg. of pure hormone. The makers provide a booklet explaining the mode of employment and possible clinical applications of the preparation. Promising results have been recorded with the use of testosterone for the relief of symptoms due to enlargement of the prostate. The dosage recommended is a series of injections on alternate days of doses of 5 to 25 mg.

IODO-CAFFEINE ELIXIR

Elixir iodo-caffeine compound (Evans Sons Lescher and Webb Ltd.) contains caffeine sodium iodide, together with hyoscyamus, valerian, and sal volatile. It is recommended for various purposes, including that of producing a sedative action in chronic asthmatics.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY DECEMBER 3 1938

THE STATUS OF PATHOLOGY

The decision to endow a lectureship as a memorial to the late Professor E. H. Kettle has been generally applauded. The first of these lectures, an abstract of which appears on page 1162, was delivered by Professor W. W. C. Topley, who is peculiarly qualified to undertake this task by his long and intimate association with the man whom it commemorates, and by community of ideas with him on the subject of the lecture itself. "The Place of Pathology among the Medical Sciences" was a matter upon which Kettle had very decided views; they were, in fact, principles which guided his life. That a deeply considered pronouncement on this subject in its widest bearings should be interwoven, as in this lecture, with repeated tributes to his influence and achievements would be in his own estimation the most gratifying honour which could be paid to his memory. Kettle was one of those men to whom the science of pathology owes the respect in which it is held, and the breadth of his outlook, the patience and determination of his experimental work, and his insistence on securing adequate evidence before drawing conclusions, are held up as a model to which future effort should conform.

Professor Topley traces the development of the sciences on which medicine is based, and in particular of those which the term "pathology" embraces, and makes a number of proposals for the advancement of their study and for the advantage of those who follow it. The keynote of almost all of these is a greater breadth of individual outlook. No one deserves to be called a pathologist who, although his chief occupation may ultimately be morbid anatomy, bacteriology, or pathological chemistry, does not know his way about in the other two of these spheres; and this means that in the early stages of his career he must be permitted and indeed encouraged to employ himself in more than one of them, and perhaps to explore the "profitable borderlands" between them. The medical bacteriologist should not be simply a botanist, either merely pursuing a systematic study of a primitive form of plant life or employing a number of laboratory tricks which happen to be useful in the diagnosis of disease: the host is his

concern as well as the micro-organism, and the whole of the changes produced by infection in the body are within his province and should be an object of his study. The dependence of one branch of pathology on another, and the advantages of familiarity with both, have never been better illustrated than in Kettle's work on the tissue changes produced by infection, and notably his study of the infective element in silicosis. If there is one of these branches of which a far wider diffusion of knowledge is necessary, it is certainly morbid histology: not only is a mental picture of the bodily changes in disease helpful in the intelligent pursuit of any type of pathological work, but, as Professor Topley points out, there is a serious dearth of really proficient morbid histologists. This may not be due only to the counter-attraction of the experimental field, as he suggests, nor even to the limited income entailed, but also to the lack of opportunities for systematic advanced study. There is, in fact, no course in this subject corresponding to that for the diploma in bacteriology, and neither experimental research, owing to its necessarily limited scope, nor the haphazard experience of a year or two in the diagnostic laboratory and the post-mortem room, can altogether take its place.

The same underlying idea permeates the proposals made for the betterment of undergraduate education. The student's career is at present a series of stern and disconnected exercises, and when at last he finds himself among patients he is apt to think that everything without a bearing obvious to himself on how to handle them is thenceforth irrelevant and safely to be forgotten. To break down the barriers which must exist in his mind between the pre-clinical sciences and clinical medicine would indeed be a step forward, and neither the ruthless pruning nor the collaboration between widely separated departments which it would involve is impossible. The teaching of pathology itself, how, and more particularly when, it should be done, has been much debated recently, and there can be few who are satisfied with the present position. In most schools it is an "ancillary" subject in the clinical years, not over-kindly treated in the matter of available time, and competing for the student's attention with the new human interest and obvious practicality of clinical work. It is too apt to be regarded as a matter of merely learning to identify things, whether under microscopes or in bottles, or to perform tests which are useful in diagnosis. Let there be no mistake about the claims of the pathologist for his subject. It is not ancillary to medicine but the foundation of it. The learning of pathology is not a mere academic exercise and an extension of facilities for diagnosis;

it is a fundamental necessity for comprehending the processes of disease, and hence for intelligent and progressive treatment or prevention. For this claim to be sustained the teaching of pathology must be of corresponding nature; it must be related to medicine in the way meant by Boyd when he writes: "A world of disordered function lies revealed in any lesion if we only have the eye to see it." It must, in fact, make the student think, and future progress depends on there being more with inquiring minds—men who are not content to know that a thing is so but want the reason why.

Another problem with which Professor Topley deals is the rival claims of teaching, routine diagnostic work, and research. The majority of pathologists in medical schools—including bacteriologists, for whom the difficulty is perhaps greatest—have to apportion their time between all these three things, if indeed the last of them is not crowded out altogether by the other two and perhaps by administrative work as well. Each of the three can benefit from the others, but only on condition that none claims too large a share of his time. For the individual pathologist this is the most pressing problem of all, and any future development which lightens his burden will bear fruit in more than one direction.

PLAY THERAPY AND CHILD GUIDANCE

Since the establishment of the kindergarten system in the latter part of the last century it has been increasingly recognized that the play of children serves a special function, not only in their education but in the maintenance of their mental health. Given otherwise similar conditions, those children who have opportunity to play freely—whether in the streets or in the nursery—tend to develop a more active and stable disposition than those bounded in this respect. Conversely, observation of a child at play provides material for accurate diagnosis of the mental and emotional condition. The well-balanced child is one who can happily express in play the fantasies which are the essence of his emotional life: the play of the maladjusted or neurotic child is commonly inhibited, compulsive, or ambivalent in character. With the development of psychopathology, especially during the last ten years, further investigations into the play-life of

childhood have revealed its importance as a presentation of the unconscious as well as the conscious mind, a form of expression comparable to the verbal free association of adults and therefore of inestimable value in the fields of child guidance and child psychiatry. And so of recent years there has arisen in child guidance clinics and elsewhere

a service known as play therapy. From the recognition of these two factors—the place of play in the mental hygiene of childhood, and its value in the treatment of children's psychological disorders—play therapy has developed both as a means of prophylaxis and as a method of treatment. It includes the organization in schools of activities that may encourage a high standard of mental health, and the treatment in child guidance clinics, hospitals, and elsewhere of the psychogenic disorders of childhood—with extremely encouraging results.

In 1924 Karl Abraham declared that "the future of psycho-analysis is in play analysis." In 1928 Mrs. Klein published a paper describing the use of toys and miniature figures in play analysis. Work has also been done at the Institute of Child Psychology, and in various child guidance clinics, especially the Tavistock Clinic, methods of play therapy have been studied and developed. The method employed is founded on the one hand upon extensive study of child development—physical, mental, and emotional—and on the other hand upon an intimate personal knowledge of unconscious processes, normal and abnormal. This latter, comparable to the knowledge of physical anatomy gained by dissection, is regarded as an essential preparation for the play therapist. In the treatment of psychological cases play therapy, though it owes much to the research work of the psychoanalysts of childhood, is developing its own technique, adapted especially to the necessary limitations of work under out-patient conditions. Equipment, which is by no means costly, is designed to provide objects corresponding to those of importance in the child patient's experience and fantasy, a miniature cosmos which he himself can direct. Among these objects are elemental materials such as sand and water; small figures representing the family constellation; houses and fences that enclose or protect; objects that take in and eject, such as pumps or mincing machines; cars, aeroplanes, and their instruments of power; plastic material and the means of graphic and dramatic expression; constructional toys; also objects which by their shape, size, or colour may be charged with special symbolic significance. No suggestion is given as to the child's choice or use of material. He is completely free to do what he likes with it, so long as he injures neither himself nor the observer. It has been found advisable to keep the apparatus as simple as possible.

The free use of such material by a child or group of children in the presence of a benevolent but neutral adult who is sufficiently trained to encourage expression while avoiding stimulation or suggestion is in itself beneficial and may even prove enough for the resolution of minor psycho-

logical disorders, especially those of social maladjustment. For more severe cases a different method is employed, and the child is always treated individually. Two major factors have to be considered: the reactions of the child to the therapist, and the situations presented in the play itself. The validity of these, as representing the child's emotional life with its underlying emotional conflicts, depends upon the skill of the play therapist, who has to provide in the treatment room an atmosphere in which the child may feel so secure, so free from blame or praise, that he may dare to be himself and to express himself happily without self-consciousness. Obviously such conditions can be created only by an observer who is emotionally secure and competent to assess his own reactions, since the dramatic play of small children tends to arouse the emotions of childhood dormant in the adult, as illustrated by the classic example of the father who monopolizes the toy trains of his small son. The therapist must acquire a technique for controlling voice and movement (established so firmly as to be automatic) comparable to that of the surgeon in avoiding the introduction of any fresh infection during operation. An inappropriate phrase or gesture may be as dangerous as an unsterilized swab. In psychological cases, obviously, *ars est celare artem*, so that the child perceives only a friendly individual who seems ready and competent to help him. Under such conditions of security the child can express in his play and tolerate those feelings which were once repressed because intolerable to a weak developing ego—and which, because their natural outlet was blocked, have become a source of emotional hypertension. As the play situations develop and unconscious conflicts are revealed these are re-presented to the patient in his own terms—that is, in the objective terms of his play, but in relation to the reality situation. In this way bogies of the unconscious mind come from their dark corners into the daylight, and, seen in their true perspective, lose the terror of the undefined. At the same time the child's natural forces making for mental health are enabled to reassert themselves; there is a gradual reorientation of the whole personality, and the re-establishment of confidence, happiness, and mental vigour.

Although statistics are not so far available, results of this method appear very satisfactory over an age range of 2½ years to 17 years, the amount of play relative to verbal expression normally decreasing with the age increase. Suitable types of cases include: (a) nervous disorders—depression, anxiety, phobias, obsessions, night terrors, sleeplessness; (b) habit disorders—enuresis, nail-biting, etc.; (c) educational difficulties—backwardness in intelli-

gent children, unmanageable behaviour, bullyings or timidity; (d) delinquency—pilfering, truancy, lying, etc. Among adolescents treatment has been successful with cases of a schizoid type, as well as with conversion hysteria, and in severe stammering when a verbal approach is difficult. It does not appear suitable for the majority of delinquents over 10 years old, although in some of these cases it has proved useful. It must, however, be remembered that the emotional balance of the child may, like his metabolism, be easily upset and quickly readjusted. Much caution must therefore be exercised in putting forward claims for cure when all that has happened is that therapy has coincided with the natural resolution of a transient disturbance. This must especially be borne in mind in any attempt to assess the results of treatment statistically.

THE TESTING OF DISINFECTANTS

We have referred before to the proceedings of those committees of the British Standards Institution which have been engaged during the past few years in defining standard methods for the testing of disinfectants. The need for authoritative definition of such methods can only be fully appreciated by those who have had experience with them; a variation of technique in any of a dozen directions may considerably affect the coefficient obtained, whereas rigid adherence to a method prescribed in every detail will give results which are constant within narrow limits. The original request for standardization of the Rideal-Walker method came from the disinfectant industry, which has for many years accepted this test as an index of the quality of its products. Disinfectants are sold with a guaranteed Rideal-Walker coefficient, and discrepancies between the results of tests by seller and buyer, due often to varying technique, have been the cause of frequent disputes. The object of this effort was attained by the publication of a British Standard Technique for the Rideal-Walker test in 1934 (British Standard Specification No. 541; 1934). Whatever the commercial convenience of this achievement it did not meet the need for a recognized method of testing disinfectants under more severe conditions, designed to imitate those in which most disinfectants are expected to act. It is fairly generally known that a major obstacle to disinfectant action is what is usually called organic matter, represented, for example, when the object is the disinfection of excreta, by all the material of which faeces are composed. In the presence of such material some types of disinfectant which yield high Rideal-Walker coefficients become completely ineffective, and even disinfectants of coal-tar origin lose much of their activity as judged by the minimum dilution required for complete sterilization. Moreover, this proportion varies with their composition, being least with phenol and solutions of cresols, and greatest with emulsions of tar acids of higher boiling-point, of which many proprietary disinfectants of this kind are composed. The Chick-Martin test, which actually employs faeces as added organic matter, has

been used to a limited extent for many years as an index of practical disinfectant power, and it forms the basis of a second method, which has now been made the subject of a British Standard Specification.¹ The principal modification which this method has undergone is the substitution for dried faeces of a suspension of yeast; this change was originally proposed by L. P. Garrod,^{2,3} and has several advantages. Dried human faeces, besides being unpleasant to prepare and work with, are of necessity inconstant in composition, whereas a suspension of commercial yeast is readily prepared, can be adequately standardized in composition, and represents organic matter in both dissolved and particulate form similar in nature to material of excremental or vegetable origin which a disinfectant may encounter in practice. It remains to be seen how far this test will be adopted by public health authorities and other users of disinfectants. The sphere of its applicability is not defined in the specification, but it will doubtless be recognized that the test is appropriate only for disinfectants to be used outside the body. The definition of suitable methods for assessing the capacity of surgical disinfectants is a task which has not yet been begun, nor is it, so far as we are aware, even in contemplation.

IMMEDIATE DIAGNOSIS OF DIPHTHERIA

Apart from microscopical examination of the swab, which is often unsatisfactory, the bacteriologist can rarely be certain of the presence of diphtheria bacilli in less than eighteen hours, with the result that in practice the clinician must decide for himself whether or not to give serum treatment. Working under the direction of Professor A. Sordelli at Buenos Aires, Dr. A. Manzullo⁴ not only has succeeded in considerably shortening the time required for a bacteriological diagnosis but has evolved a method by which an immediate diagnosis may be made at the bedside. He observed that if the swab was inoculated into a tube of blood-tellurite medium, prepared according to Horgan and Marshall's formula with the omission of the agar, and incubated at 37° C., black spots developed on the swab within about three hours. Microscopical examination of these spots showed that they contained diphtheria bacilli; confirmation was afforded by plating and by guinea-pig inoculation tests. It was further observed that these spots appeared on actual pieces of pseudomembrane that had been torn off while taking the swab, and that only pseudomembrane containing diphtheria bacilli reacted in this way. Manzullo conceived the idea of applying a tellurite solution to the pharyngeal pseudomembrane *in situ*. In practice he makes up a 2 per cent. solution of potassium tellurite in distilled water, dissolving it at a temperature below 40° C. After soaking the swab in the solution he applies it to the pharyngeal exudate, taking care not to touch the tongue during the process. If the patient suffering from active diphtheria blackening of the exudate is visible in five to ten minutes; otherwise no change in colour occurs. In seventy-two out of

seventy-five cases complete agreement was reached between the results of this bedside method and the bacteriological diagnosis in the laboratory. One or two precautions are necessary. The tellurite solution must not be kept for more than a month. False results may be obtained if methylene-blue has been applied locally or if the patient has used a mouth-wash containing tannic acid or hydrogen peroxide. It must be understood that the method is essentially one for the diagnosis of active diphtheria, whether of faucial or of nasal type; it is useless for the detection of healthy carriers. How early in the disease the reaction becomes positive is not stated, but even if it does no more than afford confirmation or otherwise of the clinician's diagnosis in cases presenting definite changes in the pharyngeal mucosa it should prove of considerable value.

WHAT IS VITAMIN P?

Szent-Györgyi and his co-workers^{1,2,3,4,5} claimed that the "natural" vitamin C of plant tissues, particularly of fruit juices, was superior to the synthetic ascorbic acid in the treatment of various pathological conditions characterized by increased permeability of the capillaries, and that this superiority was due to the presence in the fruit juices of a substance which they named vitamin P and identified as a flavone, "citrin." Its effect on vascular permeability was then demonstrated in guinea-pigs, which when fed on a scorbutic diet plus 1 mg. "citrin" daily lived longer than guinea-pigs fed on the diet alone. Later it was shown that "citrin" was not a pure substance but a mixture of crystals of hesperidin and an eriodictyol glucoside, the former in much the larger proportion. When hesperidin was obtained in pure form it was found to have vitamin-P influence on guinea-pigs. Thus it was concluded that the syndrome of experimental scurvy in guinea-pigs was due to a deficiency of both vitamins C and P. Zilva,⁶ however, in repeating this work on guinea-pigs found that daily doses of 1 mg. of "citrin," of a mixture of $\frac{2}{3}$ mg. hesperidin and $\frac{1}{3}$ mg. eriodictyol, or of 1 mg. of purified hesperidin did not delay the onset of scurvy or the fatal termination of the disease in guinea-pigs on a scorbutic diet. Moreover, a daily dose of 0.1 mg. or 0.2 mg. of ascorbic acid (doses much lower than the minimum prophylactic dose) produced a condition resembling that obtained by Szent-Györgyi by a dose of 1 mg. of "citrin." Zilva's guinea-pigs had received a pre-experimental diet at least as good as that declared by Bentsath⁷ to be necessary for the demonstration of the vitamin-P effect, and yet he failed to obtain it. Lotze⁸ has recently made a full investigation of two commercial preparations of "vitamin P" and of nearly pure hesperidin prepared from them. His examination was made by spectroscopic and chemical means, by animal experiments, and by clinical trials on human subjects. Chemical and spectroscopic tests showed that

his preparations did not fully accord with those used by Szent-Györgyi and his co-workers. However, he found that, including the nearly pure hesperidin, they had a certain amount of biological action; it was very much less than that of vitamin C itself, but it enhanced the action of vitamin C when used in combination with it. In his clinical trials he observed that the commercial preparations exerted an influence similar to that reported by the Hungarian workers. Lotze therefore suggests that the active preparations, and perhaps "nearly pure" hesperidin itself, contain some substance belonging to the flavone group which is not without biological activity, and that the preparations found by other workers to be inactive, though apparently very like the active ones, did not in fact contain the active substance. At present, therefore, it seems to be less a question of whether vitamin P really exists than of what vitamin P really is.

DID COLUMBUS DISCOVER SYPHILIS?

The origin of syphilis has been hotly disputed by medical historians for many years, but the consensus of opinion has gradually hardened so that now it is generally accepted that it was introduced into Europe from the Western Hemisphere. Dr. Victor Robinson has summarized in an interesting article¹ much of the evidence in favour of the American origin of the disease which remains valid, although foreign scholarship and American patriotism have combined in the attempt to remove the origin of syphilis from the New World. One single case of syphilis in pre-Columbian Europe would throw the entire American theory to the ground, but that single case has not been produced. On the other hand, within a year of the return of Columbus from the island of Haiti it had spread from Spain to Italy and France. The evidence of contemporary Spaniards is extremely significant. Dr. Robinson quotes the words of Capitan Gonzalo Fernandes Oviedo y Valdes, a man who was appointed supervisor of the foundries of gold in America and who lived in Haiti. He says: "Many times in Italy did I laugh, hearing the Italians say the French disease, and the French calling it the disease of Naples; and in truth both would have hit on the right name if they had called it the disease from the Indies. . . . Great was the wonder produced in all that saw it, not only because the disease was contagious and horrible but because many died of this disease." Then there is the testimony of the celebrated Las Casas, the one humanitarian among the Spanish explorers. He devoted most of his long life to the welfare of the Indians and was known as the Apostle of the Indies. He agrees with Oviedo in stating that the natives of Haiti gave syphilis to the white race. Both Oviedo and Las Casas state that the Indians treated it successfully with guaiacum. Another authority is the Spanish surgeon Ruiz Diaz de Isla, who published a book in 1539 called the *Treatise Concerning the Serpentine Disease*, which was the name he gave to syphilis. By the time he wrote this book he had had forty years' experience of syphilis—that is, from 1492 onwards—and believed he had observed over 20,000 cases. He,

too, maintains that syphilis was unknown in Europe until Columbus and his crew returned from Haiti (which he discovered during his first transatlantic journey) and infected the inhabitants of Barcelona. He says the "serpentine disease" appeared and was seen in Spain in 1493, in the city of Barcelona, "which city was infected, and subsequently all Europe and the Universe in all known and communicable parts." Unfortunately Ruiz Diaz de Isla is by no means an absolutely satisfactory witness, for after the above statement, which would seem to be unimpeachable evidence for the American origin, he immediately contradicts himself by asserting that his "serpentine disease" is identical with the lichen of the Greeks and the kiss-spread mentagra of Pliny. Moreover, while he shows signs of being an acute clinical observer, inasmuch as "three species" of his "serpentine disease" approximate the three stages of syphilis famous to us all, he almost simultaneously destroys our confidence in him by stating that he has seen cabbages suffering from the disease! A further interesting suggestion we do not remember to have seen made before is that Columbus himself may have suffered from syphilis, for his good health prior to his discovery of America contrasts vividly with his subsequent invalidism. He suffered from arthritic and ophthalmic complaints, prolonged fever, swollen legs, and cardiac dropsy. Although none of these is conclusive evidence, there are modern clinicians who believe that Columbus in discovering America also discovered syphilis, and was one of its early victims.

THE GORDON TEST FOR LYMPHADENOMA

The intracerebral inoculation of rabbits with autolysed suspensions of lymph glands from cases of lymphadenoma was originally performed by M. H. Gordon in an attempt to transmit a hypothetical infective agent to the animal, which responds in no characteristic or significant way to any other method of inoculation. The result was a fatal encephalitis with highly characteristic clinical features, and it was only caused by glands from cases of lymphadenoma; on the other hand, it was not transmissible in series, and could therefore not be accepted as indicating the presence of a micro-organism. Thus what originally held out some promise of throwing light on the aetiology of the disease became a diagnostic procedure, and has been extensively used, for this purpose. An important step towards an understanding of the mechanism by which this effect is produced in the rabbit was the demonstration by Friedemann that it can also be produced with extracts of normal bone marrow. Since this observation a large variety of tissue extracts has been tested, and it is now generally believed that a positive result depends on the presence in the tissue used of certain types of cell, the autolysis of which liberates the encephalitogenic agent. A recent paper by McNaught¹ gives reasons for concluding that the encephalitogenic property depends solely on the presence of eosinophils. According to this author there is perfect correlation between the degree of infiltration with eosinophils seen in section and the result of the rabbit test, and the proportion of cases of lymph-

¹ Brit. J. Derm. Syph., November, 1938.

¹ J. Amer. med. Ass., 1938, 111, 1280.

adenoma in which the test is positive and of those in which eosinophilic infiltration is present is the same—namely, 70 per cent. He also obtained positive results in the rabbit with extracts of tissues containing many eosinophils but quite unrelated to lymphadenoma. If this conclusion be accepted, it would appear that the test gives no information not obtainable by the simple inspection of a section; but experience suggests that the matter is not quite so simple, and there is experimental evidence that the active agent is not confined to the eosinophil. Edward,² although his results with eosinophilic material anticipate those of McNaught, also obtained positive results with suspensions of neutrophil leucocytes in the form of sterilized pus and of lymphocytes from the blood in lymphatic leukaemia. Until the nature of the agent has been more clearly defined it will perhaps be wise to withhold final judgment on its source.

REFORM OF THE PENAL LAWS

The Criminal Justice Bill which was recently introduced in the House of Commons by the Home Secretary shows the great influence which medical, and especially psychological, science is exerting in the treatment of criminals. The importance of the probation system is recognized by provisions for its reorganization and extension. The sentencing of young offenders to imprisonment is to be greatly restricted and later, when other methods have become available, practically abolished. Remand centres and remand homes are to be established to receive young persons who are considered to need special medical observation and who would otherwise be remanded in prison. Two interesting new experiments are proposed. As an alternative to fines or short terms of imprisonment, young people convicted of minor offences will be required to attend at a "compulsory attendance centre" during half-holidays or in the evening after work, when they would otherwise be enjoying themselves at the pictures or watching a football match. It is to be hoped that they will be put to some intelligent occupation at these centres; if they are merely made "to hang about" the experiment will do more harm than good. The relevant sections mention appropriate occupation and instruction, but do not appear to make these obligatory. The second innovation is the Howard Homes for young persons who do not require Borstal training but ought to be taken away from bad associations. They will go out to their ordinary employment during the day but be under discipline at other times. Corporal punishment will be abolished as a judicial penalty and only survive as part of prison discipline under strict limitation. Persistent offenders will be liable to receive sentences of corrective training and preventive detention. The medical examination of offenders when they are before the court will be much facilitated by the provision which enables the court to remand an offender on bail with a condition that he submits himself to medical examination, the cost being paid by the State. Courts have hitherto had the power to certify an offender as a mental defective but not as a person of unsound mind; magistrates are

by this Bill given power to certify a person of unsound mind on the certificates of at least two doctors. There is no provision that one of these shall be on the panel of practitioners approved for this purpose by the Board of Control, and an amendment should be made to bring the section into line with the Mental Treatment Act, 1930. Courts placing on probation an offender who suffers from some form of mental illness or abnormality which is susceptible to treatment will be able to make a condition of the probation order that he shall submit to mental treatment, either as an in-patient or as an out-patient. This will regularize such action as was taken a year ago by the Wakefield magistrates in placing an offender on probation with a condition of residence in a mental hospital. "Criminal lunatics" become "State mental patients," and their asylums "State mental hospitals": Broadmoor will be transferred to the Board of Control. The Bill has been severely criticized in some quarters for making a conviction necessary before a probation order is made. The present absence of this necessity has been regarded as one of the best features of the probation system. The Bill contains a clause which nullifies any disqualification which would attach to sentence, but this would not cancel the stigma which conviction carries in the eyes of most of the community. Apprehension has also been expressed at the power to be given to magistrates of courts to sentence young offenders to Borstal. Doubtless these and other points will be hotly debated in committee. On the whole the Bill reflects a great increase in humanity and appreciation of psychological fact. It is for the medical profession to provide sufficient persons with the skill which would qualify them to assist the courts in the disposal of offenders who would profit from treatment under medical direction, and to advise the courts on the measures most likely to prevent the offender from returning.

To-day, Friday, December 2, at 5 p.m., Professor R. E. Kelly delivers the Bradshaw Lecture on "Recurrent Peptic Ulceration" before the Royal College of Surgeons of England. On Thursday, December 8, Mr. H. A. T. Fairbank will give the Robert Jones Memorial Lecture on "Increased and Decreased Density of Bone, with Special Reference to Fibrosis of the Marrow"; and on Thursday, December 15, Sir Humphry Rolleston will give the Thomas Vicary Lecture on "The Early History of Morbid Anatomy in England."

The ninth annual reports of the National Radium Trust and Radium Commission for the year 1937-8, including a statistical report, are published this week as a pamphlet of sixty-six pages by H.M. Stationery Office (Cmd. 5883, 1s.). Reference to their contents will be made in a later issue.

We regret to announce the death of Dr. William McDougall, F.R.S., professor of psychology in Duke University, North Carolina, formerly Wilde Reader in Psychology at Oxford and professor at Harvard; and of Dr. Harold Pritchard, emeritus physician to the West London Hospital.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

FRACTURES AND DISLOCATIONS OF THE SPINE

BY

HARRY PLATT, M.D., M.S., F.R.C.S.

Mechanism of Spinal Injuries

The majority of fractures and dislocations of the spine occur at the three levels of greatest mobility: (a) in the upper cervical region (atlas, axis); (b) in the lower cervical region (fifth, sixth, and seventh cervical vertebrae); and (c) in the dorso-lumbar region (eleventh and twelfth dorsal and first and second lumbar vertebrae). A brief consideration of the effects on the spine of certain forces is essential to a clear understanding of the principles of treatment.

Vertical Compression.—This mechanism is chiefly responsible for the crush fracture of a vertebral body produced by a fall from a height on to the buttocks or heels. The force is transmitted through the anterior column of the spine, and is expended on a single vertebral body, usually the twelfth dorsal or first lumbar, which collapses and becomes wedge-shaped (Fig. 1, A). If the

FIG. 1.—A: Compression fracture—wedge deformity. B: Hyperflexion fracture—comminution. C: Hyperflexion fracture-dislocation.

force is more widely diffused slighter degrees of wedging may be seen in the vertebrae immediately above and below the site of the main crush. Another well-known but uncommon clinical type of compression injury is the fracture of the posterior arch of the atlas produced by a blow on the top of the head.

Hyperflexion.—In this mechanism the spine is suddenly bent forwards by violence applied either to the upper part of the back and shoulders or to the head. The crush fracture of the coal-miner produced by a fallen roof is the most familiar example of this type of injury. Hyperflexion fractures take one of the following forms: (a) collapse of a single vertebral body, often with comminution and rupture of the underlying intervertebral disk (Fig. 1, B); (b) the classical fracture-dislocation of the lower cervical or dorso-lumbar region in which the pedicles are broken or, less frequently, a dislocation takes place at the intervertebral joints. This is followed at once by forward displacement of the vertebral body and a narrowing of the spinal canal immediately below (Fig. 1, C). In a certain proportion of cases the displacement

undergoes spontaneous recoil. In fracture-dislocations accompanied by cord injury the violence is often unusually severe, and well-marked bony displacement is the rule. The neural lesion is coincident with the bony injury and may be a simple contusion or a complete transection of the cord. Where bony displacement persists the cord becomes attenuated at the site of the protrusion.

Rotation.—Rotation, combined with flexion, is the force producing sUBLUXATIONS or dislocations of the cervical spine unaccompanied by fracture. These uncommon injuries, of which several types are described, may result from comparatively trivial violence. The best-known type is the unilateral forward sUBLUXATION at the level of the fifth or sixth cervical. Involvement of the cord or nerve roots is rare, except in the bilateral dislocations, which may be immediately fatal.

Hyperextension.—Hyperextension fractures of the spine are exceedingly rare. In this type of injury the compression force falls on the posterior part of the anterior column. If the broken vertebral body is comminuted the risk of protrusion of a fragment into the spinal canal is considerable.

Hyperextension of the head combined with vertical compression is the mechanism concerned in fractures of the odontoid process of the axis.

First-aid Treatment of Spinal Fractures

Although the treatment of fractures and dislocations of the spine demands all the resources of the modern fracture clinic the fate of the injured individual may be influenced for good or ill by methods used in administering first aid or during the transport of the patient to hospital. A study of the mechanics of spinal fractures suggests that a movement or posture which tends to perpetuate the crushing force in a compression fracture, or to increase the displacement in a fracture-dislocation, will be harmful or even disastrous. In the great majority of spinal fractures the dangerous movement is forward flexion of the trunk or neck. It is important, therefore, to lay down certain rules of conduct for the guidance of those who may find themselves responsible for the emergency treatment and transport of an individual with a suspected or proved fracture of the spine.

1. The public should be taught that an injured person who has lost the use of his arms and/or legs should not be lifted or carried before the arrival of a doctor or trained ambulance worker.

2. In a fracture of the dorso-lumbar region the patient should be carefully rolled over on to his face and a pillow placed under the upper part of the chest. This manoeuvre alone may be sufficient to reduce a fracture-dislocation. In lifting him on to the stretcher the position of extension of the spine should be maintained. If no stretcher is available at the site of the accident—as at the seam-face in a coal-mine—the victim should be carried to the first-aid post in the prone position.

3. When a spinal fracture is accompanied by a severe chest injury, a head injury, or by fractures of the lower limbs, the prone position may be impracticable or dangerous. In such circumstances the spine should be extended by placing

a firm support under the back at the level of the injury. During transfer to the stretcher care must again be taken to avoid any movement of flexion.

4. In a fracture of the cervical spine the prone position is also contraindicated. Extension should be temporarily obtained by placing a small pad underneath the neck. It should be remembered that lifting the head to enable the patient to drink from a cup is a dangerous action. When a patient with a high spinal fracture is moved, firm traction should be applied to both the head and the lower limbs.

5. On arrival at hospital, if the patient is not severely shocked, radiographs should be obtained without delay. All films should be taken without altering the position of extension for a single moment.

Recent Crush Fractures

The exact anatomy of a spinal fracture should be clearly defined in both antero-posterior and lateral radiographs

FIG. 2.—Davis (a) and Watson-Jones (b) methods of reduction of crush fractures by postural hyperextension.

before deliberate reduction is attempted. The deformity of a crush fracture should be corrected in all patients who are young or in the prime of life, and who may reasonably be expected to return to arduous occupations. Reduction aims at restoring the full vertical height of the wedged or comminuted body.

In the case of compression and hyperflexion fractures in the dorso-lumbar and lower dorsal regions reduction is achieved by hyperextending the spine to its limit, utilizing the tension of the intact anterior common ligament as an aid to reduction and as an internal splint to maintain reduction. The simplest and most effective methods of reduction are those devised by Davis and Watson-Jones. In the Davis method the patient, lying prone, is slung by the heels (Fig. 2, a). In the Watson-Jones technique the patient is suspended between two tables with the trunk unsupported, a position which allows the lumbar spine to sag into the maximum degree of hyperextension (Fig. 2, b). For the reduction of recent fractures no anaesthesia is required. When the maximum hyperextension has been obtained a closely fitting plaster jacket is applied over a layer of stockinet. The jacket extends in front from the pubis and groins to the clavicles and is cut out behind over the upper part of the dorsal spine (Fig. 3). In this way the

hyperextended position is continuously maintained and forward-flexion of the spine is impossible. The accuracy of the reduction should be confirmed in radiographs taken in two planes. A second jacket should be applied some three weeks later when the original jacket has become less close-fitting. At this stage a check-lateral radiograph should be obtained.

It is generally agreed that early ambulatory activity should be encouraged in crush fractures of the spine. Much depends on the age, temperament, and physical condition of the patient. The younger individuals should be allowed to sit up after a few days and to walk at the end of a week. Elderly patients—and more especially those with fractures in the mid-dorsal region, where complete anatomical reduction is rarely, if ever, achieved—can with advantage be kept in bed or on a couch for the first three or four weeks.

The position of hyperextension should be maintained until there is clinical and radiographic evidence of consolidation of the fracture. This will generally mean that the spine must be immobilized and protected for not less than four months from the time of the injury. During the latter part of this period many patients are able to engage in light duties. After the final removal of the jacket a rehabilitation programme is arranged. The functional and anatomical results of the treatment of crush fractures of the vertebral bodies by the method of hyperextension are most gratifying. Seventy-five per cent. of the patients so treated should be able to return to their original occupations.

With hyperextension fractures the method of reduction described is definitely contraindicated, for the obvious reason that further hyperextension of the spine may produce cord damage. In these cases the jacket should be applied with the spine in the ordinary neutral position.

FIG. 3.—Plaster jacket maintaining hyperextension.

Old Fractures: Kümmell's Disease

In the case of crush fractures undiagnosed in the early stage or treated ineffectively, the patient may later present himself complaining of backache, persistent rigidity, or increasing deformity. This clinical picture, when appearing after a long interval, was formerly known as Kümmell's disease (spondylitis traumatica). The treatment to be considered in such cases is: (a) a period of rest followed by the fitting of a support—a course suitable for elderly patients who cannot hope to return to heavy duties; or (b) in the younger individuals the operation of spinal fusion, which is generally effective in curing the backache.

Correction of Fracture-dislocations

CERVICAL REGION

The common fracture-dislocation of the cervical spine with forward displacement at the level of the fifth or sixth vertebra calls for prompt correction. If the signs of cord or root compression are present no time should be lost. Two methods of reduction are available.

Reduction by Manipulation.—The technique devised by A. S. Taylor of New York has been successfully used for some years by many different surgeons. The patient

is placed on a fracture table and a halter applied to the head. A stout cord or rope is attached to the side rings of the halter and passed round the waist of the surgeon. With the neck securely controlled between the surgeon's hands, steady traction is now exerted by a backward movement of the body. Counter-traction is provided by the fixation of the lower limbs to the traction bars of the table. The traction force is first applied in very slight flexion in order to disengage the articular processes. When the neck is felt to elongate, the head and upper part of the spine are allowed to drop back into the position of extension. The accuracy of the reduction is checked in a lateral radiograph, and the head and neck are then fixed in a plaster-of-Paris cast.

Gradual Reduction by Continuous Traction.—This is a recent innovation which has already proved to be particularly effective in the reduction of fracture-dislocations of the upper part of the cervical spine (Mackenzie, Turner, Cone, Crutchfield, and others). The traction is applied direct to the skull either by special tongs which perforate the outer table or by wires passed through drill-holes and connected to a cross-bar (Fig. 4). The

FIG. 4.—Skeletal traction on the head in fracture-dislocations of the cervical spine. (The diagram inset shows the application of the tongs to the skull.)

points of attachment to the skull should be chosen so that the pull is in the long axis of the cervical spine. Counter-traction is provided by raising the head of the bed. A weight of 10 to 15 lb. may be required for a short time to correct gross displacement.

In recent fractures the reduction takes place almost immediately. In fractures of some weeks' standing correction is a gradual process. In cases without cord injury, if the patient is in good condition, the tongs can be removed after the reduction has been confirmed in the lateral radiograph and a "Minerva" plaster jacket applied. In severe cord lesions it is wise to keep up light traction (that is, 4 or 5 lb.) for ten to fourteen days, and if the patient survives this critical period to apply the plaster at a later stage. This method of skeletal traction enables a paraplegic patient to be nursed with safety and comfort. In this respect alone it undoubtedly represents an important advance in the technique of treating fractures.

Skeletal traction is of course inapplicable if there is infection of the scalp.

It will be realized that the reduction of a fracture-dislocation of the cervical spine by either of the methods described requires special training and a high degree of manipulative skill, as well as the necessary armamentarium.

DORSAL AND DORSO-LUMBAR REGION

In hyperflexion fracture-dislocations without cord injury reduction by hyperextension should be carried out as soon as the patient is fit.

In paraplegic cases, although the fate of the cord has been determined from the moment of the injury, the correction of gross displacement is no less essential. The precarious condition of many patients during the first few days, however, makes the ordinary reduction and application of a plaster jacket a distressing and hazardous undertaking. Where for good reasons it is necessary to veto or postpone any attempt at complete correction the patient should be placed in the hyperextended position in a well-padded bivalved plaster bed in which he can be turned repeatedly without flexing the spine. If an air mattress is used hyperextension can be obtained by inserting a rolled blanket under the mattress at the level of the lumbar spine (Byron Stookey).

In a small proportion of fracture-dislocations of the dorso-lumbar region, accompanied by severe injury to the lower end of the cord and roots of the cauda equina, reduction by manipulation or by gravity is impossible owing to interlocking of the dislocated articular processes. In such cases hyperextension not only is ineffective but is also a dangerous manoeuvre, which may inflict grave additional damage on the cord or nerve roots. When this type of dislocation is recognized the correct procedure is to operate and remove the superior articular process of the vertebra immediately below the displaced body. This allows the articular processes to be realigned and the displacement of the body corrected.

Treatment of Paraplegia

The modern methods of reduction of fracture-dislocations have entirely supplanted the operation of laminectomy. Despite increasing experience in the handling of spinal fractures the mortality in cases with neural involvement continues to be high. A number of patients die in the first few days from shock or from the effects of other injuries. Of the survivors, some die during the first few weeks from such complications as urinary tract infection, bedsores, or pneumonia. Patients who reach the stage of reflex cord function may live for many years, and in the less severe cord lesions a useful measure of control over the paralysed limbs may be regained.

The prevention of bedsores and contractures and the care of bladder and bowel function demand skilled nursing. The areas of skin in contact with the air mattress or plaster bed at points of greatest pressure should be constantly shifted by gentle stroking. The prevention of urinary infection is the greatest responsibility of all. In a few patients the bladder may be emptied by pressure, but in the majority some form of regular catheterization is necessary. This must be done with the strictest aseptic precautions. A safe and effective method is to use an in-dwelling catheter, changed every five or six days. The bowels should be regulated by mild aperients or enemata, and over-distension should be avoided. The paralysed limbs should be supported in the standard positions, and after the stage of spinal shock is

H. Ensing (*Nederl. Tijdschr. Geneesk.*, 1938, 82, 5381) records his observations on seventy-nine cases of actinomycosis treated at the Gröningen Academy Hospital during the last thirty years. The localization of the disease was as follows: neck and jaw, forty-six cases; thorax and lungs, two; abdominal wall and abdominal organs, thirty-one. Of the fifty-one male adults thirty-one were agricultural labourers, while the occupation of the remaining twenty brought them much less in contact with the soil (clerks, factory workers, and others). The ages of the patients ranged from 15 to 35. There were fifteen adult women patients, and of thirteen patients under 20 even were males and six females. In more than half the cases infection took place by the buccal mucosa. In twenty-three of the thirty-one cases of abdominal actinomycosis the primary localization was in the ilco-caecal region, in two in the sigmoid, and in one in the rectum, while in the other five the primary focus could not be discovered. Recovery took place in 88 per cent. of the cases in which the neck and jaws were involved, and in 28.5 per cent. of the abdominal cases.

DEMONSTRATION OF MECHANICAL RESPIRATORS

In view of the general interest in the use of the apparatus popularly known as the "iron lung" in the treatment of poliomyelitis and paralysis after diphtheria, the Public Health Department of the London County Council arranged at County Hall a demonstration of the several types of mechanical respirators used in its institutions. The Council began using mechanical respirators in 1934, the year in which the first English-made "iron lung" was introduced, and now it has sixteen of them in operation, including at least one in each of its acute infectious diseases hospitals. One of the objects of the demonstration was to encourage other local authorities to equip their own hospitals in this manner. The Council is constantly being asked for the loan of its apparatus, and with the best will in the world it is not always possible to comply.

Since the design of the original Drinker respirator in Philadelphia, a number of refinements and accessories have been added in this country with a view to making the apparatus safer and more convenient in use, more comfortable for the patient, and more effective in treatment. Some of these were shown embodied in the

L.C.C. Drinker model. More recently a machine identical in principle with the Drinker respirator has been designed, having a chamber of laminated wood instead of metal, together with other modifications more especially to facilitate nursing. This new respirator is mounted on a tripod stand with a worm-and-sector tilting device. It has a constant-speed motor, with bellows driven at rates of 18, 22, and 28 respirations per minute, and all the working parts are enclosed in a steel cylinder which protects the mechanism from dust and eliminates noise. In the working out of this cheaper, lighter, and more transportable respirator the staff of the Council has had the advantage of consultation with Mr. Both, an Australian technician.

Another apparatus shown was an improved jacket respirator. The original jacket was widely used in Australia during an epidemic of poliomyelitis last year, and was described and illustrated in a paper by Professor A. E. Burstall of Melbourne in the *British Medical Journal* of September 17, 1938 (p. 611). It consists of a one-piece aluminium cuirass enclosing the trunk of the patient from neck to waist. The Council staff believes that the modifications it has made in this apparatus have resulted in a great improvement on the original and has elimin-

ated some of its admitted disadvantages. It now consists of an aluminium jacket shaped to the thorax and made in two pieces, back and front. These halves join at the sides by thumbscrew nuts on an air-tight joint. The shape of the armholes has been altered to afford more freedom, the design of the rubber diaphragm has been modified, and an escape valve provided to regulate the depth of the respirations. The respirator is operated by a one-eighth horse-power motor designed to drive a suction bellows at a fixed speed of 20 double strokes per minute. The jacket respirator does not replace the cabinet—in which the patient is wholly enclosed save for the head and which may be essential in the treatment of certain cases—but it has advantages in simplification. The patient with this appliance can, of course, be nursed in an ordinary bed. Another apparatus on view was the pulsator for prolonged artificial respiration, designed by

Mr. R. W. Paul at the suggestion of Sir William Bragg.

Coincident with the demonstration came the announcement of Lord Nuffield's offer whereby hospitals in the country having cases requiring respirators may be equipped. Like all Lord Nuffield's gifts, it is marked by largeness and a sense of what is needed. It must be borne in mind, however, that the respirator is still in a state of evolution, and probably many modifications will yet be made, just as new uses will be found for it (already it is suggested in cases of

drowning, carbon monoxide poisoning, partial electrocution, mine explosion, and war casualties). When presently it is stabilized it may be a much simpler affair than the still quite formidable arrangements which were on view in London. It will be unfortunate if Lord Nuffield's most generous offer has the effect of stereotyping the present patterns.

[The photograph reproduced is by the Photographic Department, L.C.C. Southern Laboratory.]

Case of diphtheria with respiratory paralysis being treated in mechanical respirator (tilted) at the North-Western Hospital, London County Council. Respirator designed for use in the Council's hospitals.

F. Tecilazic (*Minerva med.*, 1928, 29, 451) states that the specific action of vitamin B₁ in beriberi neuritis has suggested its use in other forms of neuritis, and records his personal observations on forty-one cases of diphtheritic paralysis. Of five severe cases of paralysis of the diaphragm and of the muscles of deglutition two recovered after three or four intraspinal injections of vitamin B₁ in the form of tetrophan, while the other three died. In the remaining thirty-six cases, which were examples of paralysis of the palate with or without general hypotonus, paralysis of accommodation, and loss of reflexes, vitamin B₁ did not appear to have the slightest effect. On the other hand, in twenty-four cases of malignant diphtheria and thirty-three cases of extensive faucial diphtheria in which vitamin B₁ was given, the incidence and severity of paralysis were much less than usual.

THE PLACE OF PATHOLOGY AMONG MEDICAL SCIENCES

KETTLE MEMORIAL LECTURE

The first lecture in memory of Edgar Hartley Kettle was delivered at the London School of Tropical Medicine and Hygiene on November 24. The lecturer was Professor W. W. C. TOPLEY, F.R.S., who chose as his theme, "The Place of Pathology among the Medical Sciences." There was a large attendance presided over by Sir John Caulcutt, chairman of the Governing Body of the British Postgraduate School, with Viscount Dawson and Colonel A. H. Proctor, Dean of the School, beside him on the dais.

Professor Topley began with a moving tribute to Kettle himself. Kettle had, he said, the rare wisdom that enabled him to keep a clear head amid the rapid emergence of new subjects and new techniques, and the adjustments that these necessitated in the older scheme of things. "He never resisted or resented them. He had an instinctive sympathy for all new things and for all young people; but in welcoming the new he did not forget the old." The lecturer quoted freely from Kettle's written papers, illustrated his successive points from Kettle's work, and said that, consciously or unconsciously, he was influenced most of all by recollections of his spoken words.

The Scope of Pathology

A growing science, said Professor Topley, not only expanded, it budded and divided. Physiology and pathology were themselves offshoots of medicine. A description of any science must be given in dynamic, not in static terms. It could never be said that pathology *is* so-and-so. It could only be said what and where it was at the moment, and which way it seemed to be moving.

In each of the biological sciences there had been a drift from the systematic study of structure and its relationship to a study of function, and from a study of any given function as an integrated whole to an analysis of the mechanisms on which that function depended. This movement was, of course, only a shift in the immediate focus of intellectual interest and effort. Structure did not become less important when viewed in terms of function; indeed, it gained greatly in significance.

Pathology, like physiology, began with the study of structure, or rather of structural changes; but it was still in this phase when physiology had undergone its metamorphosis into an experimental science. The accurate and detailed study of the changes in tissue structure associated with disease must always be an essential part of pathology as a whole; nor could a worker claim the label "pathologist" in any broad sense if he had no knowledge at all of the structural changes that are associated with disease.

If there is any danger at the present time in regard to the relative activity of the different aspects of pathology, it is a danger of too few morbid anatomists, not too many. The rapid advances made by bacteriology and immunity, by biochemistry, and by the application, as in cardiology, of physiological methods of attacking pathological problems have led so many workers into other paths that the expert histologist may soon be, if not a *rara avis*, at least a species whose future gives rise to anxiety. We cannot do without him. As a diagnostician he has an essential part to play, and he forms a firm and valuable link between pathology and clinical medicine. In the field of experimental research his potentialities are in the early stages of development; and the growing realization of this fact, particularly in this country and in America, may provide us with the records that we so clearly need.

A Question of Labels

It did not follow that pathology was morbid anatomy, or that morbid anatomists were the only pathologists. Here the lecturer thought that labelling had lagged behind practice, with results that were, or might become, unfortunate. "A pathologist must have some knowledge of structural tissue change, but he must also know enough physiology to relate abnormal structure to abnormal function, enough biochemistry to understand something of the chemical causes, or consequences, of the pathological processes that he studied, and enough bacteriology and immunity to give him some insight into the mechanisms concerned in infective disease. No man could be a master in each and all of these fields; but they were all pathology, and none of them had an exclusive right to that title.

If the common use of the label "pathology" as a synonym for morbid anatomy was misleading, the label "bacteriology," in so far as it implied a differentiation from pathology, was more misleading still. The bacteriologist, properly so called, was clearly a particular kind of botanist. He studied bacteria as such. The medical bacteriologist, on the other hand, was a pathologist who was concerned with the bacterial and virus infections of men and animals. He must spend much of his time and energy in studying the parasites; but he could not neglect the hosts. The tissue changes associated with infection were clearly within his province, and here the lecturer remarked that it would be difficult to find a better illustration of the close and inevitable relationship between morbid anatomy and medical bacteriology than was afforded by Kettle's work in the years following the great war.

Methods of Pathology

Professor Topley went on to emphasize some of the factors which differentiated pathology from most other medical sciences, except clinical medicine itself. A considerable part of the pathologist's work was still concerned with the observation of naturally occurring events not subject to experimental control. He had, therefore, in common with others in a similar position, to guard carefully against drawing premature conclusions from inadequate data, and rapid solutions were unlikely to come his way. What was less often realized was that he usually suffered from a similar disadvantage when he confined himself to the experimental field. Here he thought there was as sharp a contrast as with physiology.

It would not be a gross misrepresentation to attribute the rapid advance of physiology in the last half-century to the successful designing and exploitation of "acute" experiments. By his skill in this direction the physiologist had been able to obtain rapid answers to many of his problems; not only because experiments of this type gave their answers quickly, but because their very shortness of duration helped to eliminate the chance intrusion of many disturbing factors.

Probably a similar technique would yield valuable results to the pathologist, when he was in a position to use it, and one of the hopeful signs of the present day was the entry into the pathological field of workers who had acquired a physiological technique. But for a long time to come pathologists would be largely concerned with experiments that were as "chronic" as the processes they were designed to study, and the technique of the long-term experiment would be an essential element in their training.

Scientific research might be roughly divided into two broad categories: those inquiries that could be determined mainly by the nature of the problem to be solved, and those that were determined mainly by the nature of the technique to be employed.

"The great names and the great moments of science are associated with the transient merging of these two categories."

A technique developed in an attack on one particular problem is found to be applicable to a multitude of related problems, all of which, by their intrinsic interest and importance, are pressing for solution. Such a period occurred in the bacteriological field between 1880 and 1900, when, as Löffler put it, 'Koch shook the trees and the apples fell.' But it is seldom long before the advent of a period of diminishing returns. A new technique takes its place as one of the tools of science, but the advance on that particular front slows up until some new technique is invented. There are not many Pasteurs and Kochs, and the efficacy even of these great ones depends in part on the times in which they live, and on the developments in the several branches of science that provide them with the instruments that they exploit."

At most times and for most workers the choice was less happy. A chosen problem could be attacked by slow and relatively ineffective methods, which could be developed where this seemed possible, or a technique could be selected and applied to such problems as it was clearly fitted to solve. There was a danger of judging too much on results, and particularly on the form in which results could be presented. The neat and tidy answer to one problem might represent no more significant advance than the ragged and partial solution of another. It was a misuse of words to say that the one result was more "scientific" than the other or had been gained by more "scientific" means.

Relation of Pathology to Clinical Medicine

Neither pathology nor physiology, Professor Topley continued, could ignore the problem of clinical medicine, though an individual pathologist or physiologist might be well advised to do so. The clinician on his side could not ignore pathology and physiology. An increasing amount of clinical practice derived directly from the methods devised and from the results obtained in pathological and physiological laboratories, and these in their turn depended in large part on methods and results derived from the fundamental sciences of chemistry and physics.

For convenience, labels were attached to the broad fields of activity in medical sciences and to the people who worked in them. Boundaries had been put up which called not only for separate professorial chairs but for separate institutes. Did such separation matter? So far as research was concerned the lecturer believed that for the original worker, the man who would do the biggest things, it did not matter at all. For the ordinary man it mattered much more. It was not good that a young pathologist in his early or middle twenties should be labelled a morbid anatomist, or a bacteriologist, or a pathological chemist, and run in blinkers from that day onwards. From the point of view of the application of pathological or physiological knowledge to curative or preventive medicine he believed that the existing separation mattered profoundly. It was the main reason why medical practice and medical science failed to advance as quickly as they might. Could anything be done about the present separation of the medical sciences, supposing it to be a harmful thing? The crux was clearly education.

Integration of Medical Education

The present medical curriculum was frankly a system of almost disconnected examinational hedges. He believed that the historian of medical education in this country would regard the introduction of pathology as a tripos subject at Cambridge as a turning point, not only because there were aspects of general pathology that could best be taught at this stage in a student's career, but because the introduction of pathology of the right kind would enhance the student's interest in his physiological and histological studies, and would make clear to him, while he was pursuing them, their bearing on disease processes.

He thought that there should be introduced much earlier into education the concept of disease processes, of

abnormal function and structure, and that the teaching of the ancillary sciences should be continued much later in the curriculum. This would mean a scrapping of certain things that were now taught, but he would willingly let them go. If the student knew well those parts of anatomy, physiology, and pathology that had a direct bearing on his clinical work—if he knew them so that he could grasp their significance and discuss them intelligently—he would be a better scientist and a better clinician than if his heritage from his pre-clinical studies was a vague recollection of a partially digested mass of unappreciated facts and theories. This would help most substantially to break down the barrier of which he had spoken.

The Organization of Medical Sciences

But that was not all that could be done to break down the existing separation.

"I fancy that bricks and mortar are more dangerous things than is commonly supposed. I have a growing dislike of separate institutes where these can be avoided. Separate chairs of morbid anatomy, bacteriology, and pathological chemistry have become an obvious administrative necessity; but I profoundly mistrust the housing of this family of sciences in different buildings. Nor would I give to one more than another the right to adopt the family name of pathologist."

It would also be well to encourage men whose early training had been in one scientific field to migrate to another; and, again, to look favourably on a shift of subject-matter from one departmental territory to another.

One word of caution was necessary. In trying to abolish such barriers as already existed, the creation of new ones must be prevented. No man could compass the range of the medical sciences; nevertheless, it was possible to develop a common tradition, a common background of knowledge, and a common way of thought. This could best be done by breaking down existing barriers in the manner of which he had spoken, and erecting no new ones; and by training those who came into medicine to respect scientific method, which included accurate and critical observation, rather than to acquire, and then forget, an arbitrary collection of unrelated knowledge.

There was one factor, said the lecturer in conclusion, on which the success of all such purposes depended, and that was the personal one. Co-operation could never be forced, though it could be encouraged. "By Kettle's death we have lost one of our number who had the gift of true co-operation at its best. He had the widest interests and the widest sympathies, and was always able to view his own problems in relation to those of others. He has left behind him a memory and an example that none of us will forget."

An enthusiastic vote of thanks was accorded to Professor Topley for his lecture, on the proposal of Professor Francis R. Fraser.

Dr. Charles V. MacKay, Acting Director of the Australian Institute of Anatomy, Canberra, contributes to the *Medical Journal of Australia* of October 1 an article, copiously illustrated, on some pathological changes in the Australian aboriginal bones. This records the author's investigations into the pathology of bones found near the River Murray in southern New South Wales. The total number of bones examined was 351. Of these specimens nearly 200 were classified as periostitis, osteitis, or osteomyelitis. Dr. MacKay discusses at length the problem of the underlying causative factor which brought about such marked changes in bone architecture, and by elimination concentrates upon some form of spirochaetal infection, either acquired syphilis, endemic syphilis, yaws, or some unknown pathological entity peculiar to the Australian race. After studying the historical, geographical, and medical information at his disposal he regards venereal syphilis as the most likely cause of the lesions.

RADIUM 1898-1938

LA SEMAINE INTERNATIONALE CONTRE
LE CANCER

The International Cancer Week, organized by the International Union against Cancer to commemorate the fortieth anniversary of the discovery of radium, was formally inaugurated in Paris on November 23 by a series of notable functions.

In the morning the scientific delegates were received at the Palais de la Découverte by the great French physicist, Jean Perrin, who afterwards conducted a tour of this remarkable building, which was constructed for the exhibition held last year and contains an amazing collection of exhibits illustrating recent progress in every branch of applied physics and biology. In the afternoon the delegates were entertained to tea (and champagne) at the Hôtel de Ville and were addressed by M. le Provost de Launay and

by M. Justin Godart, the President of the International Union against Cancer.

Commemoration at the Sorbonne

The climax of an eventful day came, however, in the evening when the great amphitheatre of the Sorbonne was filled to overflowing by an immense concourse of delegates from the universities, academics, and learned societies of forty or fifty countries. M. Albert Lebrun, the President of the Republic, supported by the Ministers of Education and of Public Health, presided over the gathering, and with him on the platform were the two daughters of Pierre and Marie Curie, Mlle Eve Curie and Mme Joliot-Curie; the Marchesa Marconi; and Mlle Hertz—the daughter of the discoverer of Hertzian waves—now, alas! a refugee from Germany but living in safety in England. There were also on the platform M. de Broglie, M. Gutton, M. Langevin, Professor Roussy, M. Bezançon (the President of the Academy of Medicine), Dr. Bécélère (the doyen of French radiologists), Dr. Carter Wood of New York, and Professor G. P. Thomson (the distinguished son of the celebrated J. J.). British scientific institutions were represented in full force: the British Empire Cancer Campaign by Professor Woodburn Morison, Mr. Malcolm Donaldson, and Mr. Cecil Rowntree; the Ministry of Health by Colonel Smallman; the Medical Research Council by Professor Russ; Edinburgh University by Mr. Shaw; the Royal Institution by Professor Hopwood; and the Royal Cancer Hospital by Dr. Kaye.

Homage to the Curies

The proceedings were opened by the President of the Republic with a speech in which he paid an eloquent tribute to the achievements of science and in particular to the work of the Curies. His speech was followed by a broadcast from Warsaw by M. Moscicki, the President of the Republic of Poland, which on the whole came off quite clearly but was from time to time disturbed by German interference. The French President then replied in a speech broadcast to Poland. After other speeches from eminent French scientists Dr. Gendreau, the Canadian delegate from Montreal, gave great pleasure by his eloquent panegyric of the Curies, and worthily maintained the prestige of the British Empire by proving that he could easily hold his own with the great orators of France in their own tongue.

There is no question that France well knows that science should be honoured and knows well how to do it. Few who had the privilege of being present at the Sorbonne last week will forget the picture it presented. Cuirassiers of the Guard posted round the amphitheatre lent an unaccustomed touch to a scientific gathering, while the uniforms of high officers of State, the orders, stars, and ribbons of the ambassadors, the dresses of the women, and the robes of the Papal Nuncio all combined to produce a colourful and impressive spectacle.

One of the objects of the International Cancer Week is to raise funds for the International Union against Cancer, and a special set of surcharged stamps bearing the portrait of the Curies has been issued. It is satisfactory to learn that the sale of these stamps has already exceeded expectations and that the funds of the International Union will benefit accordingly.

The scientific business of the Cancer Week has continued daily and many papers bearing more particularly on various aspects of x-ray and radium therapy have been submitted. On the first day Mr. Cecil Rowntree gave a brief account of the anti-cancer effort of Great Britain, during the course of which he conveyed a message of good wishes from the Minister of Health and referred to the Bill which Dr. Elliot proposes shortly to introduce in the House of Commons, in order to implement the proposals with regard to the treatment of cancer foreshadowed in the King's Speech at the opening of Parliament.

GREAT MEDICAL VICTORIANS
SIR SICLAIR THOMSON'S LECTURE

At a reception given by the President of the Royal Society of Medicine (Sir Girdling Ball) and Lady Ball on November 29, Sir SICLAIR THOMSON gave an address on "Medical Notabilities of the Victorian Age, as Seen by *Vanité Fair*." The periodical mentioned published for many years a series of cartoons entitled "Men of the Day." These were drawn by two artists who signed themselves "Spy" and "Ape." "Spy" was the late Sir Leslie Ward, a sensitive draughtsman, and "Ape" was an Italian artist, one Carlo Pelligrini, who scored a great success with his first caricature of Disraeli in 1869. Appended to each of the cartoons was a short biographical sketch signed "Jehu Junior." This was Thomas Gibson Bowles, the editor of the periodical and sometime member of Parliament. The Library of the Royal Society of Medicine possesses thirty-one of these cartoons which have as their subjects prominent physicians and surgeons of Victorian and Edwardian days. These were shown as lantern slides, while Sir Sicclair Thomson made a few remarks on the careers, personalities, and reputations of the artists' "victims."

Good Vintage Years

The year of Waterloo and the year immediately following it saw the birth of three great figures in British medicine—Sir William Jenner, Sir William Gill, and Sir Richard Quain. Of the first of these Sir Sicclair Thomson said that although a court physician he had not the bedside manner described in fiction and often represented on the stage as characteristic of a successful consultant. His chief characteristic was robust common sense. His manners were somewhat autocratic, and he allowed no sentimental illusions to blind him to the frailties of human nature. He once told his class at University College Hospital that there were two things they were bound to encounter—death and ingratitude. On another occasion, slapping his trouser pockets, he told his students that when he began practice one of those pockets was for fees, the other for affronts. But as soon as he had made his way he buttoned up the second pocket. The reference to him in *Vanité*

Fair stated: "Sir William Jenner is one of the most successful practitioners of those obscure devices to which the strongest are occasionally forced to resort, and which, even now, often consist of curing a man of one disease by giving him another."

Sir William Gull, another court physician, was somewhat of an agnostic in therapeutics, as many men were in those days following the ages during which patients had been drenched with drugs. One of his wise sayings was: "Never write a prescription which causes you any anxiety." He was a man who had decided dramatic sense, and the great Charcot, who was a psychologist, called him "*un grand poseur*." Sir Richard Quain, the third of the trio, was often in consultation with Gull. On one occasion Quain detailed a line of treatment, but Gull said that all the patient required was a warm bed, whereupon Quain remarked that his colleague was well known for his habit of sending his patients to a warm place. Gull once suggested a little reserve in prognosis, adding, rather pontifically, "We must remember *Populus vult decipi*." To which Quain replied, "I quite agree; the public does not like to be gulled."

Sir James Paget, who was born in 1814, was a scientific surgeon, a great teacher, a delightful writer, and a captivating orator. For the benefit of younger members of the profession Sir StClair Thomson quoted his opinion on the prospects of a career:

"Anyone with a safe knowledge of his profession and free from such faults—that is, idle, time-wasting, unbusinesslike, unpunctual, unevill, unable to work with others—may be as certain of success in the practice of medicine or surgery, or both, as in any other business of life; or even more certain, because his prosperity may be very nearly independent of that of others."

A Later Period

Next came a group of men who were born during the first ten years of the Victorian era. Sir Francis Laking was medical attendant on three sovereigns, and a man who "could walk with kings nor lose the common touch." With his cartoon it was stated, "He is a courtly gentleman who knows his business," and Sir StClair Thomson, who knew him fairly well, said that this was an excellent description. Sir William Dalby, who was in his time the leading aural surgeon in this country, had more the appearance of a leisured squire than of a leader in a surgical specialty. His brief biography in *Vanity Fair* stated:

"He is well known in smart society, and he dines at all sorts of houses. He is a member of the Garrick . . . excellent company, and finds time to play whist every day before dinner."

Such was the well-rounded life of a London specialist in the spacious days of Queen Victoria. Sir Alfred Cooper also had a large and fashionable West End practice, and was a keen sportsman—rode in the Row every morning, shot in Scotland every autumn, and, said *Vanity Fair*, "is known as 'Alfred' and is as cheery as he looks."

Two surgeons of a later period, only a few years gone from us, who were also immortalized in these cartoons, were Sir Alfred Fripp and Sir John Bland-Sutton. Of the former Sir StClair Thomson said that he was a happy and successful man and one of the best-known surgeons in the late Edwardian and early neo-Georgian periods. Full of vigour and responsiveness, always ready to please and to be pleased, unsparing in his care and anxiety for his patients, and with an attractive personality, it was not surprising that these qualities, added to his skill, care, and experience, secured him a large, fashionable, and lucrative practice. He had the good fortune to come in on the flowing tide of surgery which followed the long-delayed but sudden and complete acceptance of Listerian principles in London. Sir John Bland-Sutton also was fortunate in that his rise in his profession coincided with the adoption

of Listerism. He had the insight, training, and courage to be one of the pioneers in the great realm of surgery to which Lister had pointed. The biography described him as "the scientific mind incarnate, a born enemy of ambiguity and indecision, dangerously fond of facts, an able and experienced debater, a cold and logical writer, and an accurate observer. He is impatient and blunt, and makes no pretence of winning converts by any of the drawing-room virtues."

The Nestor of the Profession

Sir StClair Thomson's last example was one happily still with us—Sir Thomas Barlow, who was the subject of "Spy" more than thirty years ago. "Jehu Junior" stated that books always formed the bulkiest part of Sir Thomas's baggage, that he was interested in archaeology, that he consumed meals rapidly and at irregular hours, that he had an unequalled reputation in the treatment of children, and knew exactly what to say to anxious parents. "He is tactful in consultation, and avoids his neighbour's corns by doing his duty." To this Sir StClair Thomson added that his name would live in Germany, where a disease which he discovered was known as "*Barlows'sche Krankheit*."

In conclusion Sir StClair Thomson said that he trusted his disjointed remarks had revived some happy memories among any Victorians present. These successful medical men of what the French were beginning to call "*le grand siècle*" showed that the strenuous life was not a modern invention, but had to be led by all who loved their profession.

"In our days, when medicine is rapidly becoming more and more scientific, the doctor is perhaps better able to mould his career without devoting so much care to developing and applying the art of his profession. But he will better succeed, and be a happier man, if he preserves his humanity, always remembering that the patient's first anxiety is to be cured, and not merely studied."

THE SOCIETY OF APOTHECARIES

HONOUR FOR SIR BUCKSTON BROWNE

At the Yeomanry Dinner of the Society of Apothecaries of London, held on November 22, the Honorary Freedom of the Society was conferred on Sir Buckston Browne. In introducing him to the Society, Mr. L. V. CARGILL, the Senior Warden, said that the Honorary Freedom was the highest honour the Guild could bestow, and Sir Buckston had been unanimously elected to the only vacancy both for his eminence in the profession and his munificent gifts to medicine and to science. Sir Buckston, he continued, was born in April, 1850, and came to London from Owens College, Manchester. He had been house-surgeon to Erichsen, and was associated with the celebrated lithotomist, Sir Henry Thompson, who operated on Napoleon III. Sir Buckston had founded a scholarship in memory of his son, had given Downe House to the nation, and to the Royal College of Surgeons had presented and endowed the Buckston Browne Research Farm to the extent of some £100,000; he had also instituted an annual dinner at the College of Surgeons. After this speech the Master, Dr. Reginald Hayes, conferred upon Sir Buckston the Honorary Freedom of the Society.

A Medical Family

In expressing his deep gratitude to the Society for this honour, Sir BUCKSTON BROWNE said that he was the fifth and last practitioner of medicine in his family. His great-grandfather was born 225 years ago and was an apothecary in the town of Derby, and married into the family of the Buckstons. His great-grandmother's brother fought

at Culloden beside Wolfe, who subsequently became the famous general known to history. Continuing his interesting family history, Sir Buckston said that his great-grandfather had served seven years as an apprentice to his great-great-grandfather, and in 1797 went to London and presented himself for examination to the Company of Surgeons: this was the common way of entering the profession in those days. Finally Sir Buckston said that he himself always determined to become a doctor and came to London at the age of 18 for that purpose.

In proposing "The Society of Apothecaries," Sir GEORGE CHRYSIAL, secretary of the Ministry of Health, said that he dined in this hall and with this great and beneficent corporation with greater pleasure than with any other Company of the City. He referred to the forecast of a method used in modern medicine when at Epidaurus Aesclepias arranged for serpents to bite his patients. The sons of Aesclepias, he was glad to record, went into administrative medicine. Referring to the past struggles between the Society of Apothecaries and the two Royal Colleges, he observed that the Royal College of Surgeons had recently made the Past Master of the Society its President, and he congratulated Mr. Hugh Lett on attaining these two distinctions.

In reply, Dr. HAYES said that it was just forty-three years ago that he had attended his first Apothecaries' Dinner. The Society was founded in the seventeenth century as a craft guild, and assisted research by providing a scholarship, and among other activities showing that the Society was adaptable to modern conditions he referred to the mastership of midwifery and to the founding of the Register of Medical Auxiliaries. Dr. Hayes paid a tribute to Dr. Cecil Wall as the archivist of the Society.

Reform of the 'Curriculum'

The Junior Warden, Mr. T. B. LAYTON, proposing "The Guests," said that there was one subject of interest to them all—namely, the medical curriculum—and all would agree that this needed revision. Some six years ago a conference was held under the guidance of three of their Honorary Freeman on the curriculum, and it was soon agreed that this was seriously overloaded. A report had been produced which went the way of most "blue books." He had long pondered over this report, and had concluded that "some large subject" should be transferred from the students' curriculum into the graduate period of medical education. He proposed that the subject should be obstetrics. This was a revolutionary idea, but he hoped that they would give it serious consideration. He coupled the toast with the names of Dr. E. H. T. Nash, President of the Society of Medical Officers of Health, and Dr. Adolphe Abrahams, Dean of the Medical School attached to Westminster Hospital.

In reply Dr. NASH said that in ten years' time there would, in his opinion, be a great change in the relations between the public health service and the general practitioner and specialist. He felt that the general practitioner was being left out more and more in deliberations at the centre. He deeply deplored this. Dr. ABRAHAMS replied in a characteristically witty speech in which he said that the Deans of the Medical Schools look upon the Yeomanry Dinner "as one of our best perquisites." Referring to "a dithering of deans," he said that this was about the only chance they had of meeting each other.

E. Massobrio and A. Appiano (*Minerva med.*, 1938, 29, 381), who record three cases of pernicious anaemia in patients aged 61, 72, and 59, state that clinically psychoses arising in the course of pernicious anaemia are prone to considerable variation. They agree with other writers who hold that there is nothing characteristic in these mental syndromes. In all three cases complete disappearance of the psychoses—which had led to the patients being sent to an asylum—followed the administration of raw liver by mouth and the intramuscular injection of liver extract.

Nova et Vetera

THE JUBILEE OF THE "BRITISH JOURNAL OF DERMATOLOGY"

This periodical appeared for the first time in November, 1888, under the joint editorship of Malcolm Morris (afterwards knighted) and H. G. Brooke, and celebrates its jubilee with a special number of historical interest. Many readers will be glad to see in this jubilee number a photograph of Mr. H. L. Jackson, who has now himself been fifty years with Messrs. H. K. Lewis, the firm which publishes the *British Journal of Dermatology*. At the time of its foundation there were but few special medical journals in England. The doyen of such publications is the *British Journal of Ophthalmology*, which first appeared in 1882 under the name of the *Ophthalmic Review*, and was followed in 1887 by the *Journal of Laryngology*. The *British Journal of Dermatology* was a good many years junior to the corresponding publications both on the Continent and in America. It is rather remarkable that although the foundations of modern dermatology were laid in London at the beginning of the nineteenth century by the exertions of Robert Willan and Bateman, there was no special society devoted to its study in this country until 1882, when the Dermatological Society of London was founded by Stowers and Sangster, who were the first two joint secretaries. During the first six years of that society's existence there was no periodical specially devoted to diseases of the skin, and the general medical journals only gave a very scanty and grudging hospitality to the subject.

During the first years of the existence of the *British Journal of Dermatology* the chief objective was the morphological differentiation of the multifarious diseases of the skin and accuracy in their diagnosis. In a very large number of cases the practical problem before the dermatologists was the question whether the eruption was syphilitic or not. Although long before the era of the Wassermann reaction and the demonstration of the *Spirochaeta pallida* in the dark-ground field, that generation of physicians became extremely proficient in making the correct diagnosis. Later on the advance of pathology contributed a great deal to elucidating the problems of skin disease. The bacteriologists demonstrated the aetiology of the common septic diseases, while the mycologists showed that not only were the recognized forms of ringworm but also many other inflammatory conditions of the skin formerly relegated to the vast and amorphous collection known as "eczema" really due to pathogenic fungi. In this connexion the work of Colcott Fox, Adamson, and Whitfield has been outstanding. Fifty years ago cutaneous therapeutics were by no means powerful.

A Mirror of Therapeutic Progress

Most of the advances in the treatment of skin diseases have come from outside. It has been the privilege of dermatologists to grasp and adapt the weapons provided for them by the physicists and chemists. In 1900 Queen Alexandra gave the first Finsen lamp to the London Hospital, and under Dr. Sequeira a famous and successful dermatological department was developed. Almost simultaneously Freund and Schiff began to use x rays therapeutically, and their methods were soon studied and extended in British hospitals. It was about this time too that radium first made its appearance on the therapeutic

scene. A pioneer paper on this subject appeared in the *British Journal of Dermatology* by Louis Wickham of Paris in 1906. A little later the chemists began to contribute a series of powerful therapeutic compounds, the first of which was salvarsan—the famous 606—the dramatic effects of which will never be forgotten by those who were witnesses of its introduction into medicine. Later they demonstrated the therapeutic qualities of gold, and still more recently they have given us sulphonamide and its modifications. Perhaps the most important contribution to dermatological therapeutics emanating entirely within the medical profession has been the treatment of varicose and traumatic ulcers of the legs by means of adherent elastic bandages, which we owe to Dickson Wright. This method has relieved, and indeed cured, many thousands of sufferers from one of the most distressing and disabling of all non-fatal complaints. All these advances may be traced within the columns of the journal whose jubilee we are now celebrating.

One of the landmarks of the progress of dermatology in this country was the formation of the London School of Dermatology at St. John's Hospital in 1923. It is a remarkable fact that Stowers, who in 1882 had been successful in forming the Dermatological Society of London, and in 1894 the Dermatological Society of Great Britain and Ireland, which did not confine its membership to specialists but admitted all interested in skin diseases, was again the prime mover in the formation of the London School of Dermatology. In accomplishing this task he had great difficulties to overcome, and only great tact and perseverance brought success to his efforts. The formation of the school was celebrated by a dinner given to Stowers on October 10, 1923. The Jubilee Number before us will be found extremely interesting by all those who are connected with the study of the progress of dermatology, and we venture to think it also appeals to the wider medical public. It is embellished by portraits of the dermatological heroes of the epoch.

Reports of Societies

PSYCHOLOGICAL FACTORS IN PHYSIOTHERAPY

In the Section of Physical Medicine of the Royal Society of Medicine on November 18, Dr. COLLIS HALLOWES presiding, a discussion was held on psychological factors in physiotherapy.

Dr. H. CRICHTON-MILLER said that a compromise attitude towards disability—the conscious wish to be well associated with the unconscious wish to be ill—was commoner among patients than was usually supposed. There were two fallacies to be avoided: one that the will to be ill was equated with malingering; the other that the will to be ill was based on rational considerations. Physiotherapists were specially interested in this subject because physical treatments tended to be long and expensive, and therefore the more to be desired by patients of a certain psychological make-up. There were patients who pursued an interminable course of physical treatments from motives other than a desire for cure. It might not have occurred to the physiotherapist that the patient whose fibrositis was so resistant to treatment was for some obscure reason anxious to continue his or her visits. The unconscious gratification derived from the treatment might be stronger than the desire to be well. The cost of treatment was not necessarily a deterrent. The discontented ménopausal wife of the affluent man found a satisfaction in exacting from her spouse the doctor's fees. Even when the treatment, such as electrical treatment,

induced pain, it was possible that to the patient a form of torture had a hidden and morbid fascination. There were patients, especially females, who "enjoyed" painful symptoms, and to whom cure was an unwelcome discontinuance of pain. Chief among these were the hypochondriacs. The essence of hypochondria was a compulsive expiation. The original factor was repressed guilt which called for absolution or expiation, and made any form of suffering, such as insomnia or pruritus, to be desired.

A familiar patient was the one who had had to endure scepticism on the part of his family or his doctor. Such a patient sought vindication, and exulted when a specialist gave the opinion that an operation was necessary. The inevitable spectacular character of some forms of physiotherapy gave patients a comfortable feeling that their complaints were shown to be valid and their family's scepticism was rebuked. Thus the popularity of physiotherapy might sometimes be based on considerations of this kind, and depend more on personal prestige than on therapeutic value. The seekers after Christian Science and spiritual healing were often really in search of cure by magic. Not that these cults, whether orthodox or heterodox, all partook of magic; many of them were analogous to good psychotherapy, but the patient attracted to such forms of cure craved for that superiority which was associated with initiation into any obscurantist cult. Dr. Crichton-Miller also reminded the physiotherapists of a psychological difficulty among themselves. Every specialist in a sense had an unconscious bias towards his own department, and in the case of physiotherapy there might be an equally unconscious bias owing to vested interest in equipment, though it was far from his mind to suggest that the physiotherapist tended to become a panacea-monger, only that the specialism was rather more liable than others to that unconscious bias which tended to warp diagnostic discrimination.

Psychology of the Cripple

Dr. R. G. GORDON described possible reactions of the cripple to his condition. A very common reaction, though perhaps not so common as it used to be, was resentment against society and a development, as a compensation to the disability, of a spirit of aggressiveness. It was to be found in Shakespeare's conception of the hunchback Richard III:

"Deform'd, unfinished, sent before my time
Into this breathing world, scarce half made up,
And that so lamely and unfashionable
That dogs bark at me as I halt by them.
... since I cannot prove a lover ...
I am determined to prove a villain."

It was probable that something of the psychology of Kaiser Wilhelm II depended on his crippledness from birth paralysis. The physiotherapist if confronted with this aggressive attitude must try to make his patient see that he had to adjust himself to his crippledness, and that it was to his advantage to modify his resentment. Then there was the cripple who was in a chronic state of irritability because of pain; the more irritability he exhibited the more sensitive his nervous system became, and thus a vicious circle was established. Other patients accepted their disability in a state of apathy, and again a psychological approach was necessary, with re-education for social life; some sank into extreme despair, and suicide became a possibility. Dr. Gordon believed that the normally constituted person did not commit suicide; suicide was proof of a psychopathic mentality. Finally, there was the desirable attitude towards the crippled state, such as was exemplified by President Franklin Roosevelt, who not only exhibited determination to overcome the disability, but had shown, especially in recent events, his sympathy for and desire to help the unfortunate. Each patient must be taken as a separate problem. Some sort of occupation in which a use could be found for the disabled limbs was desired. The physiotherapist also should

learn with which patients, and at what stage of their treatment, he himself could in a measure fade out of the picture. Sometimes the change over to a less impressive person than oneself, provided one kept the psychological elements of the case in mind, was desirable.

General Discussion

Dr. J. B. MENNELL took up a reference by Dr. Crichton-Miller to "railway spine." He had been taught to believe that this was a psychological entity, but since he came to know something about differential diagnosis he had changed his opinion and was now convinced that there was often a definite physical lesion, and that so long as this was untreated the psychological lesion would persist. Dr. C. B. HEALD remarked that he had been puzzled occasionally by finding that a treatment which he had adopted more or less in despair did good when it had no business to do good. What was the explanation? Dr. WILFRID EDGECOMBE referred to a certain class of patients at spas, not hypochondriacs but commonly called neurasthenics, whose sole occupation was their health. Was it well to rob these people of their one interest in life? Dr. DRURY PENNINGTON asked how the "obsession" of the specialist for his specialism was to be overcome. Dr. P. P. DALTON mentioned the profound effect of the mind on rheumatic disease. He had recently seen a patient in whom some readjustment of her family life had led to immediate clearing up of deformed finger-joints. Dr. G. D. KERSLEY spoke of the association of gout with worry. Dr. DAWSON, taking up the question of self-murder, said that he had seen at a seamen's hospital Chinese patients in whom clinically no disease at all could be discovered, yet within three days they were dead. Was it an example of the will to die? Dr. KERR RUSSELL spoke of the reactions of the physiotherapist to the fact that in his specialty, unlike most others, there were large numbers of unqualified people doing practically the same work. Dr. C. W. BUCKLEY said that no single cause accounted for rheumatoid arthritis. Here was an agent of low virulence which in the ordinary individual produced no ill effects, but constitutional factors, type of musculature, the stance, and various matters of that kind came in. Dr. W. YEOMAN mentioned patients in whom acute gout was apparently induced by worry, also a patient who had had two attacks of generalized psoriasis, the first during the war, when he was extremely worried, and the other during the recent crisis. The PRESIDENT said that many people who undertook physical treatment only did so in the last resort when they were already in a state of chronic invalidism. Had they come earlier physical treatment might have done them good much more rapidly.

Dr. CRICHTON-MILLER, in replying, said that he was not prepared to admit with Dr. Gordon that all suicides were of unsound mind. There were people who took their own lives who could not be considered unsound. A great deal could be said about spontaneous death amongst Orientals, but there was no doubt that the will to be ill, the will to recover, and the will to die were factors to be taken into consideration. As for "railway spine," he agreed that there were some cases which no amount of compensation would clear up until the physiotherapist had treated them, but there were others which no amount of treatment would improve until the compensation question had been adjusted.

E PSYCHIATRIST AND THE CRIMINAL LAW

A joint meeting of the Medico-Legal Society and the Section of Psychiatry of the Royal Society of Medicine was held on November 24, His Honour Judge Earengay presiding. The subject of discussion was "The Place of the Psychiatrist in Relation to the Administration of the Criminal Law."

Dr. R. D. GILLESPIE, in opening, discussed the place of the psychiatrist in magistrates' courts. The magistrate apparently, in dealing with a number of charged persons—most of them probably first offenders—had no means of knowing about their state of mind unless the offender

appeared obviously ill or had been reported by a police official as suspected of mental disease. There were precedents for a better system in some courts of the United States, to which a psychiatrist was permanently attached with the duty of examining the offenders psychiatrically, especially after conviction and before sentence. The mere appearance of a prisoner for a few minutes in the dock was an impossible situation from which to single out the individual who was a psychiatric problem, and a night or two in the cells afforded only a slightly better basis for observation. A psychiatric report could be both brief and simple and a useful guide to a magistrate wishing to impose as appropriate a form of sentence as it might be in his power to give. It had been suggested that there should be legislation to obtain a routine psychiatric examination of certain classes of offenders—for example, sex offenders. Except in so far as it might be useful to have legislation of this kind introduced in the hope of obtaining wider facilities later, Dr. Gillespie said that he would prefer to see wider powers given so that convicted persons might receive sentences founded on a survey which at least included the psychiatric aspect.

The M'Naghten Rules

Later in his remarks Dr. Gillespie addressed himself to the M'Naghten rules. That judges themselves found the rules unwieldy and unreal was, he said, shown by the way in which they appeared to refrain from applying them. But so long as the rules remained in force it seemed to be the duty of psychiatrists to interpret them literally, and not to strain their conscience and distort their use of language in order to try to achieve an impossible task—that of moulding this abstract and unreal formula to actual knowledge. Otherwise they would bring psychiatry into disrepute and would not, in the long run, help the mentally ill. It must remain for the legal machinery to see that no ultimate injustice was done. As a matter of fact, it must only rarely happen that there was any fundamental difference of opinion between the psychiatrists who appeared for the prisoner and the prison medical officer who appeared for the Crown. A joint report would often be possible, or, if that was not legally desirable, separate reports could be submitted beforehand, and the psychiatric witnesses examined and cross-examined on them. If this were coupled with judicial recognition of the fact that the dividing line between sanity and insanity was not sharp, and that there were in consequence degrees and indeed kinds of responsibility, the position would rest more certainly upon the facts, including the psychiatric facts, rather than upon a formula.

Mr. ROLAND BURROWS, K.C., Recorder of Cambridge, said that in his view the answer to the problem set for discussion was implicit in the very form of words setting out the subject-matter. The place of the psychiatrist must be assistant and not dominant. By a psychiatrist he meant a person trained in medical knowledge who was specially interested in the abnormal working of the mind—mainly, if not entirely, in such abnormalities as were the result of mental disease. By the criminal law he understood the body of rules of conduct compliance with which was insisted upon by the State on pain of punishment. The content of that body of rules was a matter for the State to determine. The object of criminal proceedings was primarily to ascertain whether the accused was proved to be guilty or not. Underlying this was the principle that organized society must insist upon a standard of conduct to which members had to be made to conform. The object of medical treatment, on the other hand, was the prevention, cure, or alleviation of some bodily ailment.

In Mr. Burrows's view the M'Naghten rules had stood criticism and would continue to stand it for many years to come. They could be readily understood and applied by persons who gave their minds to the subject. Some members of the medical profession, faced with people suffering from mental trouble, committed themselves to a definition of insanity which would prevent anyone from

being classed as sane. They suggested that they were prepared to let anybody off the consequences of crime. By the very nature of their profession medical men when on the bench made very bad justices. His experience of medical men, with one conspicuous exception, was that they were quite incapable of weighing evidence. Their practice disabled them from taking a dispassionate view. The rules of evidence which lawyers followed were totally disregarded by doctors. Medical men suffered from a not wholly unfounded fear that they might find themselves defendants in proceedings. In his own jurisdiction he had found gross cases where persons had been before him for criminal offences, and on listening to their history he had gathered that they had been released from an institution in circumstances "in which I, an untrained layman in medical matters, would have bet any sum of money that they would commit a criminal offence after their release."

Mr. Burrows added that in the case of some unfortunate individuals he had been forced to impose sentences of imprisonment when in his opinion they ought to have been remanded to some place where they could receive mental treatment. But he had reflected that in prison they would at least have a roof over their heads, food and occupation, and medical men to supervise them. That was better than sending them out into the street.

Dr. DENIS CARROLL said that it would be of great value to administrators of the law if psychiatrists would undertake a research into groups of delinquents and the appropriate methods for dealing with them. Until comparatively recently the role of the psychiatrist was almost entirely restricted to the question of insanity and criminal responsibility, but in view of recent advances in psychiatry a court would be grossly neglecting valuable assistance if it refused to regard the psychiatrist in any role save that of an alienist. The psychiatrist might afford information which would materially affect the magistrate's view as to the usefulness or otherwise of punishment for a particular offender. That the final decision lay with the court and not with the expert on behaviour was an advantage, because it meant that the protection of the public would not be lost sight of in considering the interests of the misdoer.

Mentally Abnormal Cases in the Courts

Dr. LETITIA FAIRFIELD said that the function of the psychiatrist was to assist the court in its duty of fixing responsibility and also to advise on the disposal of the person charged. It was not the duty of the court *prima facie* to inquire into the mental state of anyone who came before it, but only to find out if a crime had been committed and the responsibility of the person charged. To attack the M'Naghten rules was like hitting a child! The only reason why they were continued in existence was that no one in the courts paid any attention to them. It was an amusing study in the art of compromise to go through the judgments of the courts during the last fifty years with regard to mental disease and capital punishment. As regards mental disease the courts were deplorable in theory, but in practice there was little ground for criticism except in dealing with some of the minor offences. In the case of certain offences such a large proportion of the offenders turned out to be mentally abnormal that on the ground of common sense and economy the courts would be justified in employing a psychiatrist before verdict and sentence. The chief of these offences were the sex category, but they included also arson, and what were known as "poison pen" cases.

She had great sympathy with the desire of the lawyer to be master in his own house, but she reminded him that his original function was to protect the prisoner from injured parties or relatives, whose vengeance was likely to be more severe than that of the law, also from the priest, and nowadays from the schoolmaster, and in certain cases and countries from the politician. The psychiatrist had been badly handicapped because by force of circumstances he was so often employed by the prisoner and was

not an official appointed to advise the court. She would welcome the official psychiatrist, not because she favoured the bureaucratic practice of medicine, but because the psychiatrist who was acting as the servant of the court had a very considerable advantage.

Dr. H. CRITCHON-MILLER, in summing up the discussion, said that apparently the two professions were going to quarrel over the M'Naghten rules for ever. The rules were only a narrow gate through which the legal profession might pass, in the eyes of their medical colleagues, into light and salvation. None of the medical speakers had claimed that the psychiatrist should have a dominant position in the courts; he would be there in the position of assistant to the magistrate or of assessor, and he hoped that the new legislation would make it possible for him to fill that role. Mr. Burrows had been very emphatic that the services of medical men should be restricted to suffering humanity. "Some of us think that humanity is apt to suffer by the slight myopia of some magistrates on certain occasions, and therefore with clear conscience we do what we can to correct these errors of refraction."

IMMUNITY IN INFLUENZA

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on November 25, Dr. J. A. H. BRINCKER presiding, a paper on "Immunity in Influenza: the Bearing of Recent Research Work" was read by Dr. C. H. ANDREWES.

Dr. Andrewes began with the assumption, which he believed to be true, that epidemic influenza was caused by a filterable virus. The term "influenza" was used to cover a variety of conditions, and it was difficult to find any precise clinical criterion as to what epidemic influenza was and was not. Experimental animals which were susceptible to infection had been found and the formidable task attempted of trying to find out whether there was any correlation between the presence or absence of a virus pathogenic for ferrets and mice and any particular clinical diagnostic feature of the infection in human beings. On the whole a virus which would infect ferrets had not been obtained from minor outbreaks occurring in years when there was no general prevalence of influenza. On the other hand, in the widespread epidemics of 1933 and 1937 it had been possible to obtain such a virus from a large proportion of the outbreaks. The cases had been divided into those of epidemic influenza and those of other febrile catarrhs; in other words, the "scrap-heap" of influenza had been taken and an attempt made to differentiate one single item as "epidemic influenza." It had not been possible as yet to say by examination of patients that one had epidemic influenza and another had not, but it had been discovered that there were certain features which distinguished one group from another. For example, the cases from which virus had been recovered had mostly an abrupt onset; it was exceptional in such cases to find a history of several days' catarrh. In true epidemic influenza constitutional symptoms had prevailed over catarrhal symptoms, there was much more malaise and aching in the limbs, and comparatively little coryza. But in the last outbreak, 1936-7, two of the features generally regarded as characteristic of influenza were not present: there was no particular tendency to protracted convalescence and the so-called post-influenzal depression, and no particular tendency to leucopenia, most of the white cell counts being within normal limits.

This point needed emphasis. It was very important in trying to appreciate how long was the immunity of man to influenza to realize that one could not rely on statements from a clinical point of view that this or that patient suffered from two attacks of influenza within, say, three months unless there was evidence that both attacks were certainly due to the virus. This could not even be said about successive outbreaks in an institution. A very

life and could assist the psychoneurotic patient to understand his illness. The limitations upon observation and recording excluded the use of the scientific method in the study of dreams. Their significance could only be seen when the concept of the unconscious was introduced. Emphasis was laid upon the view advocated by Jung—that the unconscious was the natural background of the mind. The dream was not the road to the unconscious, it was the unconscious. The aim of dream analysis and of psychotherapy was to remove the restrictions imposed by unnaturalness and artificiality. The dream, as the natural mind, could provide exactly the material required for adjustment and hence for optimum efficiency.

Many made the mistake of studying the dream as though it were an extension of conscious thinking. But the dream was rather a picturesque paraphrase of something new. Each incident in it could be thought of as causally connected with what went before. A series of dreams might be coherent and could provide not a commentary upon, but an important addition to, conscious life. When this information was assimilated the patient could take over responsibility for his life with understanding. Patients could be trained to work at their dreams in their own time and not only during the analytical session. Thus the duration of treatment could be shortened. The conflict in psychoneurotic illness was between two "goods" (using the word "good" in its philosophical sense). Hence the difficulty many had in reconciling their nature and its possibilities with that which training had commended. Dreams would show clearly how such a situation could be met.

General Discussion

Dr. CRICHTON-MILLER emphasized the point made by Dr. Bennet that analysis of his own dreams was the only means by which the analyst could keep himself sensitive to the significance of his patients' dreams. Referring to persons said to be dreamless, he described the case of a young soldier who claimed never to have dreamed and also never to have wakened with a dry bed in his life. This patient was a hypopituitary type, and after the administration of thyroid his enuresis was almost completely cured and he experienced dreams for the first time. Dr. Crichton-Miller ventured to amplify Dr. Bennet's emphatic assertion of the basic truth that we are primarily creatures. He said that the real trouble began for us when we realized that we were both creatures and creators, and that it was the incompatibility of these two aspects of life that rendered the art of living so difficult.

He went on to review the position of dream interpretation in all mental analysis. He pointed out that while dream interpretation had been described as the royal road to the unconscious, it was not the first road that had been tried, nor could it be described as the only road. Before dream interpretation was attempted, Freud had laid bare the unconscious motive through hypnosis, and to-day the Freudians regarded analysis of the transference as the most important aspect of analysis. Dr. Crichton-Miller went on to say that chemically induced narcosis in some cases served a most useful purpose, and that probably evipan or similar drugs would have a considerable vogue in mental analysis in the future.

Dr. JOHN MACKWOOD said that it was difficult to separate the dream from the sleep of the dreamer. Just as the waking life had need of sleep to restore its physical energy, so had the psychical life the need of dreams to amplify its significance. The individual owed his existence to the species, but the species owed its persistence to the individual; the two were, in fact, inseparable. Various levels of sleep were necessary to restore and maintain the balance of the physical and psychical life. The deepest levels made contact with the phylogenetic origins of the species, before the dawn of consciousness; dreams from this level were mere organic gestures.

The higher levels were those of the ontogenetic unconscious of the individual. Dreams at this level were com-

parable to analogies which had significance for all the levels of the individual psyche, if we could interpret them. Out of the dreams came synthesis. Inasmuch as any symbolization could only be interpreted for a few of the levels, he doubted if one did much more than scratch the surface by any analysis. The experience of the dream was, in itself, a synthesis. Kent defined experience as a "synthesis of the perceptions—a synthesis which is not itself contained in perception . . . in experience our perceptions come together contingently." In the dream with affect, the affective part of perception came together contingently with that part of perception which marked an object for future action. The synthesis which took place inaugurated new forms of movement in behaviour.

ENGLAND AND WALES

Hospital Contributory Schemes

The annual conference of the British Hospitals Contributory Schemes Association was held at Liverpool on November 24, 25, and 26. The principal speaker on the first day was Lord Horder, who said that contributory schemes gave hope of new life and activity to voluntary hospitals. Payment of the full cost of maintenance of the patient should be the aim of such schemes, but whether any payment should be made to the doctor out of the funds before that aim was reached was a moot point. At present the doctor's claim was being waived, but the generosity of the profession should not be too long abused. The speakers on the second day included Professor Henry Cohen of Liverpool University, who said that the position of the young consultant was much affected by contributory schemes. If he was denied opportunities because people beyond a certain income limit were admitted to these schemes, his earlier years might be a bitter struggle. Mr. S. Clayton Fryers, house-governor of Leeds General Infirmary, speaking of contributory schemes from the hospitals' point of view, considered that payment to medical staffs should be a matter for agreement between the hospital and its staff and should not be the concern of contributory schemes. It should be a direct lump-sum payment and not a percentage of moneys received from any class of contributors. Dr. J. M. Mackintosh said that in hospital development space must be found for the promotion of convalescent treatment. There must be increased provision for research and for greater elaboration of treatment. He urged the need for co-operative arrangement with local authorities in respect of patients who made no contribution. So long as treatment was not free and universal there must, he said, be some system of charge.

Royal Dental Hospital of London

The annual dinner of the staff and past and present students of the Royal Dental Hospital of London was held on November 26 under the chairmanship of Dr. F. C. Porter. In proposing the health of the hospital and the dental school, Dr. Porter spoke of his pleasure at revisiting his old school at the annual clinical "at home" which had been held earlier in the day, and he contrasted with some envy the space and equipment available to staff and students to-day with the limitations within which an earlier generation had to be accommodated. There were two things, he said, which they all desired for the dental profession—that it should receive due appreciation from the community, and that it should be worthy of such appreciation. In his response the Dean (Mr. H. Stobie) referred to the loss which the institution had suffered

during the year in the resignation of Dr. A. W. Oxford from the chairmanship; the hospital owed him a great debt for the outstanding position it now occupied. They also mourned the death of Mr. W. H. Dolamore, to whom it was due that the school became a school of the University of London. A friend of Mr. Dolamore had furnished a sum of money to establish a prize in his memory. Mr. Stobie also mentioned other events of the school year, and added that the number of students was satisfactory and the results of examinations were well up to the average. The toast of "The Visitors" was proposed by Mr. A. T. Pitts, who offered a special welcome to Mr. Hugh Lett, President of the Royal College of Surgeons, with which institution dentistry had a very close association. It was in 1860 that the College established the qualification which was held by the majority of dental surgeons. Great interest had been aroused in the proposal of the Council of the College to grant a higher diploma in dentistry, and it was with disappointment that they learned later that there were technical difficulties in the way. No body was more appropriate than the College for the granting of such a qualification, and it was hoped that the setback would be only temporary. Mr. Hugh Lett made a brief response, expressing his pleasure at being present as representing the College in view of its close connexion with dental qualification. He said that Mr. Pitts had touched upon a very important matter in mentioning the higher diploma. He could only say that the Council of the College was in sympathy with any suggestion made for the progress of dental surgery. He congratulated the hospital on the position it had attained. Mr. T. A. Coysh proposed the health of "The Chairman," and a very pleasant evening concluded.

The hospital and school presented a very busy appearance in the afternoon on the occasion of the clinical "at home." A routine operating session was held by Mr. S. A. Riddett at the adjacent Charing Cross Hospital. Mr. D. G. Walker and Mr. H. L. Hardwick gave brief lectures on the causation and treatment of haemorrhage following extraction and on the treatment of periodontal disease respectively; Miss K. C. Smyth and others showed orthodontic cases of interest; Dr. R. H. Leaver demonstrated some cases recently treated in the electrotherapeutic department, and there were exhibitions of skiagrams, photomicrographs, specimens of anatomical and pathological interest, and models of denture technique.

Joint Tuberculosis Council

The November meeting of the Joint Tuberculosis Council was held in London at the rooms of the Society of Medical Officers of Health. The chairman, Dr. S. Vere Pearson (Mundesley), referred to the great loss sustained through the deaths of Dr. L. S. T. Burrell and Dr. Jane Walker, both of whom had rendered valuable service to the Council almost since its inception. A welcome to the Council was given to Dr. R. A. Young, who was elected by the National Association in place of Professor Lyle Cummins, recently resigned. A request from the secretary of the Tuberculosis Society of Scotland for representation was acceded to. Dr. G. Lissant Cox was able to report on a successful interview with the Ministry of Health regarding the republication of Memorandum 131/T. The Council was informed that an entirely new memorandum could be drawn up at the Ministry, and that it would have a further opportunity of considering the memorandum in its final form. A brief account was given of the interview which Dr. Lissant Cox, Dr. Esther Carling, and the hon. secretary (Dr. J. B. McDougall) had with the Interdepartmental Committee on Nursing Services. Considerable discussion centred round future policy on postgraduate courses. Dr. F. Heaf, who has taken over temporarily during the absence of Dr. Brand the offices of convener of these classes, reported on the success of the two most recent efforts—at Brompton Hospital and at Heatherwood Hospital. There was a general feeling that the Council's past record in postgraduate work must be

maintained, and Dr. Heaf was asked to continue the organization of the classes until such time as Dr. Brand had recovered from his illness. During 1939 some attention will no doubt be given to postgraduate classes on tuberculosis for general practitioners, and it is hoped that a schedule will be available early in the New Year. Dr. C. O. Hawthorne brought to the notice of the Council his concern as to certain provisions in the Milk Bill now before Parliament. In his view medical opinion had been to a large extent disregarded, and after some discussion he proposed that the Milk Committee be authorized to prepare a memorandum in keeping with the past policy of the Council—as previously minuted—and that this memorandum be circulated to Members of Parliament. To this the Council agreed unanimously. A motion was tabled dealing with closer co-operation between organizations interested in tuberculosis, and Dr. R. A. Young expressed himself as being in hearty agreement with it. Professor W. W. Jameson suggested that the following resolution should be put to the Council:

"That the time has come when the relationship of the National Association for the Prevention of Tuberculosis, the Joint Tuberculosis Council, and the Tuberculosis Association to one another should be discussed, and that the Joint Tuberculosis Council will be glad to appoint representatives to meet members of the other two bodies for this purpose."

Support for this was forthcoming from Drs. Ernest Ward and Heaf, and Dr. Jessel, while agreeing with the wording, emphasized the importance of the Council preserving its identity. It was resolved that the motion be agreed to, and that the Chairman, Dr. Ward, Professor Jameson, the hon. treasurer and secretary be representatives of the Joint Tuberculosis Council in such discussions as may take place. A subcommittee had prepared a list of subjects which might be suitable for the Council for investigation. After an interesting discussion it was decided to investigate immediately "The Tuberculosis Service in Time of National Emergency" and "Whether the Use of Books in Public Libraries is a Source of Infection." Dr. James Watt (Godalming) and Professor Tytler (Wales) were appointed conveners of the two committees appointed to report.

Postgraduate Instruction in Obstetrics

The London County Council has approved a scheme for the provision, at its general hospitals, of postgraduate courses in obstetrics designed to enable general practitioners to learn the latest developments in that branch of their profession. The scheme provides for six weekly lectures, each of about one hour's duration, to be given by consultant obstetricians, six attendances at ante-natal clinics at a general hospital served by one of the consultant lecturers, and six ward rounds. The series of six lectures will be given twice a year, once at a centre north of the Thames and once at a centre south. Each practitioner attending the course will be required to pay two guineas registration fee, and it is proposed that the consultant obstetricians concerned should be paid at the rate of two guineas for each lecture.

Welsh Temple of Peace and Health

The Temple of Peace and Health built by Lord Davies at a cost of £62,000 on a site presented by the Cardiff Corporation in Cathays Park, Cardiff, was opened on November 23. The temple, of which the foundation stone was laid by Viscount Halifax last year, is a fine T-shaped building constructed in the Classic style from the designs of Mr. Percy Thomas. It stands in the Civic Centre. One of the wings will house the administrative headquarters of the Welsh National Council of the League of Nations Union, and the other the King Edward VII Welsh National Memorial Association for the prevention and treatment of tuberculosis in Wales. In a short oration Viscount Cecil said they were there to inaugurate a new centre of effort from which he hoped would radiate all over the world a new impulse for the two great causes of peace and health.

Fracture Cases at L.C.C. Hospital

The report of the London County Council's Hospitals Committee, made to the Council on November 29, contains an extract from the article by Mr. John C. Nicholson which appeared in the *British Medical Journal* of August 27, in which he described his experience as a patient in an L.C.C. hospital. Mr. Nicholson sustained a fracture of the neck of the femur, which it was advised should be nailed, and the operation was "most expertly carried out." The report adds that the operation was carried out at one of the Council's general hospitals by a senior resident medical officer.

INDIA

The Tuberculosis Campaign

Frequent allusions have appeared in this column to the increasing spread of tuberculous infections in India and to the steps taken in various parts of the country to combat it. An appeal was issued by the wife of the Viceroy for greater support of the King George Thanksgiving (Anti-Tuberculosis) Fund, and the response was so gratifying that the central committee appointed a technical committee of experts from the whole of India to formulate a general plan of campaign. A note has now been issued to all Provincial and State organizations with a view to formulating a uniform approach to the problem while allowing elasticity as regards local details and requirements. In this note it is stated that the dispensary clinic occupies a front place in the organization for combating tuberculosis in a given area and is the centre for preventive work. In urban areas such dispensaries should be established, each having its own staff under a full-time or part-time medical officer. Except in cities large enough to justify a separate building fully equipped and staffed, the dispensary should be situated within the boundaries of a well-established hospital in order to make use of the facilities for x-ray diagnosis and surgical work obtainable there. In rural areas tuberculosis clinics should be opened in existing dispensaries on fixed days each week. Emergency beds for temporary examination of suspected cases or for minor surgical treatment might be attached to the tuberculosis dispensary clinics. It is agreed in the note that, owing to the paucity of beds available in sanatoria and hospitals, domiciliary treatment must be the rule for many years to come in most cases, and the health visitors and care committees will have very important parts to play. It is possible, however, that open-air centres might be organized where patients could be kept by day, especially those coming from very congested areas. The health visitors or tuberculosis nurses should in general be specially trained women, some uniform rate of pay being arranged in each Provincial or State area. Care and after-care committees should be organized on a voluntary basis in connexion with all tuberculosis dispensaries and comprise non-officials as well as officials. The committee would meet at the dispensary, where the circumstances and difficulties of patients requiring aid would be explained, each case be considered on its merits and given financial help as required, and in some instances helped to find suitable employment. These committees would keep in touch with patients, when possible, after the completion of treatment. Appropriate training of the whole tuberculosis staff is laid down as an important function of the central and provincial organizations. School teachers in village schools could co-operate most usefully in anti-tuberculosis work if given training at Provincial and State centres. Sanatoria for tuberculosis cases might be increased on a district basis, and in cities some of their accommodation might be devoted to cases of the hospital type. In some areas the establishment of open-air schools, playgrounds, and open-air shelters is commended; in

some areas the inauguration of open-air colonies adapted to Indian conditions might also be possible. The importance of ensuring the whole-hearted co-operation of medical practitioners is emphasized, and various local Government departments and voluntary societies, such as the Red Cross Society and maternity and child welfare organizations, could afford useful assistance, representatives of such being offered seats on the council of the tuberculosis association. In allocating funds an endeavour should be made to spend not less than 75 per cent. on institutions and organizations primarily of a preventive character, the chief of which is the tuberculosis clinic. In view of the widespread slum conditions which contribute so largely to the spread of tuberculosis in towns, and of the tendency to create more overcrowded areas, it is urged that tuberculosis associations should take a leading part in stimulating measures directed towards the removal of slum conditions and their prevention in future. These associations should also be responsible for the many kinds of educative work relating to control and prevention.

IRELAND

Northern Ireland Parliamentary Vacancy

Mr. Howard Stevenson, F.R.C.S., has been selected by the Queen's University Voters' Association as the candidate to represent the University in the Northern Ireland Parliament. The vacancy has been caused by the death of Sir Robert J. Johnstone, who had been the University member since 1921. It is not anticipated that there will be any opposition.

General Medical Council

At the last meeting of the Senate of the Queen's University of Belfast it was agreed that Professor C. G. Lowry, F.R.C.S., who holds the chair of midwifery and gynaecology, should be the University representative on the General Medical Council in the place of the late Sir Robert Johnstone.

Ulster Medical Society

At the opening meeting of the session Professor W. W. D. Thomson introduced and installed his successor, Dr. J. McCloy. Dr. McCloy, in accepting the office, referred in appreciative terms to the services rendered by his predecessor in the chair, to Professor Thomson's special contributions, to his hospitality, and also to his generosity in presenting to the society the portraits of Sir Hans Sloane and Sir William Whitla. Dr. McCloy referred in feeling terms to the irreparable loss sustained by the society, and also by the whole profession in Ulster, in the death of Sir Robert Johnstone among other former members who had passed away during the year. He then delivered a most interesting address on "The By-ways of Medicine," dealing with superstitions and examples of quackery, the effects and beliefs in charms not only in Ireland but in ancient history and the less enlightened parts of the world. The address was notable alike for the sustained interest it invited and for the charm of its form and delivery. Dr. A. Gardner Robb proposed a vote of thanks to the president, which was supported by Professor W. J. Wilson and agreed to with enthusiasm.

In anticipation of the completion next spring of the new Westminster Hospital at St. John's Gardens, Horseferry Road, the Governors have approved the immediate expenditure of £10,000 upon x-ray and other electrical equipment. The greater part of the lower ground floor of the new hospital has been allocated to electrical services.

Correspondence

Prophylactic Inoculation against Pneumonia

SIR,—I would be much obliged if you could grant me space to state the facts concerned in a lengthy experiment carried out by the South African Institute for Medical Research in collaboration with Dr. A. J. Orenstein, Chief Medical Officer of the Rand Mines, Ltd., Health Department.

The experiment was to run for a number of years, and was intended to study the effect of prophylactically inoculating certain native mine labourers on the City Deep Gold Mine at Johannesburg. The mine medical organization was to be responsible for the inoculation of the natives and for the keeping of the relevant records, while the Institute prepared the vaccine and carried out all the appropriate bacteriological and pathological investigations.

In the *British Medical Journal* of October 8 (p. 761) there appeared a reference to this experiment under "South Africa: Health of Rand Miners," abstracted from Dr. A. J. Orenstein's annual report on the Central Mining—Rand Mines Group—Health Department for 1937. The report disclosed that the figures concerned in this experiment for the first three years had been submitted to Professor Dalton of the Witwatersrand University for detailed statistical analysis, and the conclusion arrived at was to the effect that the inoculation was ineffective. The first knowledge the Institute had of this publication in the annual report was its receipt, in the ordinary course of distribution. The Institute subsequently drew Dr. Orenstein's attention to some very grave shortcomings in connexion with the carrying out of the inoculations and the keeping of records in the following respects.

The essential conditions laid down for the experiment were that every alternate native on engagement at the mine was to receive three doses of vaccine, each of 1 c.cm., at intervals of approximately seven days; the uninoculated natives were to serve as controls. These conditions were not fulfilled; indeed, upon investigation it was clear that the City Deep had only received 24,000 c.cm. of vaccine from the Institute, whereas they reported to have inoculated 10,943 natives in accordance with the conditions laid down. It is obvious that, allowing for wastage and for some of the vaccine having been used therapeutically in hospital in numbers of cases, less than two-thirds of the required inoculations could have been carried out. Nevertheless the total of 10,943 natives was returned as having been "inoculated," and these are the figures which were submitted to Professor Dalton for analysis. Furthermore, no records could be given of any of the natives individually as to the number of times each had been inoculated. It is thus impossible to draw any conclusions whatever from the figures submitted in connexion with this experiment.

I am not concerned with how or why the experiment was so unfortunately handled for a period of years, but only that the results published should not be allowed to influence the judgment, in respect of the value or otherwise of pneumonia prophylactic inoculation, of those not thoroughly informed of the facts.

That the reference which appeared in the *British Medical Journal* is likely to cause some concern amongst interested investigators is evidenced by correspondence already

received by me with regard to it. (This letter has been shown to Dr. Orenstein, who agrees to its publication as representing the facts of the case.)—I am, etc.,

Johannesburg, Nov. 15.

SPENCER LISTER,
Director, South African Institute
for Medical Research.

Profound Hypoglycaemia

SIR,—I have just read Drs. J. A. Price and A. B. Raper's study of hypoglycaemia with great interest (*Journal*, November 12, p. 987). They comment with surprise that their patient at a blood-sugar concentration of 20 mg. per 100 c.cm. of blood was not in hypoglycaemic coma and remark that this has not been recorded in the literature. Perhaps not exactly, but I have pointed out (*Diabetic Life*) that the blood sugar in diabetic children may fall below 30 mg. without any symptoms. My own blood sugar has been estimated accurately as 20 mg. during an insulin experiment without any more than trifling symptoms of shakiness, and I have had similar unexpected figures in children as out-patients who showed only slight pallor. I think habituation to low blood sugars leads to a tolerance to hypoglycaemia.—I am, etc.,

London, W.t, Nov. 28.

R. D. LAWRENCE.

The Pituitary and Diabetes

SIR,—It is difficult for a retired practitioner to follow all the implications of your article under the above heading in the *Journal* of November 19 (p. 1048), but it may interest and perhaps help the men who are studying this intricate subject if I place on record the following case history:

Some fifteen to twenty years ago I had a patient (a healthy and active business man of middle age) who developed an attack of encephalitis lethargica. The attack turned out to be a mild one and he duly recovered and went to a South Coast resort to convalesce. He stayed at a luxury hotel and enjoyed to the full the sybaritism of the table. When he returned he consulted me about an excessive thirst, and I found that his urine was loaded with sugar. Now (and here is the point of this letter) he had a sugar-free urine at the beginning of his illness. I know this, because I tested it in the course of my routine examination before making a diagnosis. He was put on diet (I don't think that insulin was a practical proposition at that time) with immediate disappearance of his thirst. His urine was examined every week; sometimes it was sugar-free, sometimes not, but the latter condition could always be traced to an indiscretion in diet. He is still alive and well and under the care of my successor. To a skilled observer there is a trace of Parkinsonism in his facial expression.

In my physiology days I believe I learned that in experimental animals puncture of the tip of the calamus scriptorius produced glycosuria. Since reading your article I have been wondering if reactive hyperplasia of the anterior pituitary to an encephalitis infection in its neighbourhood had some connexion with my patient's glycosuria.—I am, etc.,

Walesby, Lincs, Nov. 20.

G. A. GRIERSON.

Infections of the Hand and Fingers

SIR,—My attention has been called to the articles that have appeared in the *Journal* on treatment of infections of the hand and fingers by Mr. Norman C. Lake in your issues of October 1, October 8, and October 15. I have read them with interest not unmingled with surprise.

For the last fourteen years I have made a special study of the surgery of the hand, and the results of my experi-

ence are embodied in a book entitled *Chirurgie de la Main*, the third edition of which has just been published by Masson et Cie, Paris. It is impossible for me to discuss here the various points that seem to me to call for remarks. One instance, however, I may mention. Mr. Lake, while accepting Kanavel's anatomical descriptions as a theoretical basis, warns the reader that he may find pus where he would not expect to find it if he accepts literally Kanavel's teachings. Yet pus in the hand does not progress in a haphazard way; it follows well-defined paths, always the same for the same starting-points. The trouble is that these paths are not those described by Kanavel. By clinical and operative observation first, then by dissections and by experimental work, it has been possible for H. Evvard and myself to map out clearly the paths of infection in the hand and fingers. It will thus be possible for the surgeon to locate the pus, to foresee the channels through which it may spread, and to make the incisions suitable for each case.—I am, etc.,

M. ISELIN,

Paris, Nov. 15. Surgeon, American Hospital of Paris.

Air Raid Precautions

SIR.—Many of us who served on subcommittees of hospitals to organize emergency medical services in the event of war were not only dissatisfied with, but extremely apprehensive of, the proposals. We were compelled to work within a framework imposed upon us by the Ministry of Health. Apparently we had no option. Adverse criticisms were made and, in my opinion, justly. While an organization was operating for the partial evacuation of the population of Greater London, concurrent arrangements were being made to concentrate enormous numbers of wounded in single buildings, which were highly vulnerable and in the very midst of the danger zone. To serve these wounded there was to be a lavish and reckless use of expert medical and nursing personnel with, again, this terrible concentration. The services of these experts were readily promised in spite of the sacrifice and the risks.

In war time if a commanding officer were given orders to occupy an untenable position by his superior officers, who were ignorant of the local conditions, he had to obey, but his first thought was to improvise what protection he could for his men. But how were we to find protection for our wounded and for our nurses? In my opinion we could give little or none. Every big hospital in London is near some legitimate objective of a bombing aeroplane, according to modern ethical standards. I believe that the unit in central London should not be a casualty clearing station unit at all, but more on the lines of a field ambulance unit, with aid posts in control of a medical officer or officers. Everyone with experience of the last war knows the implications of this and the vast difference. For one thing, instead of a large concentration of wounded, there would be a spreading out of the risks. It would admittedly be working under difficulties, but this would probably be the case anyway. No one of course knows what would happen in the event of war, but I imagine it is safe to say that for every bomb dropped on London during the last war, when flying was in its infancy, there would be hundreds in the next.

Recently one saw the strange spectacle of trenches being dug in remote country places, while we were arranging for a thousand wounded in St. Bartholomew's. Field ambulance headquarters could be scattered and housed in buildings—some parts of which would be relatively safe in the event of the collapse of the superstructure. In the neighbourhood in which I am specially interested one thinks of certain parts only of St. Bartholo-

mew's, the Old Bailey, and other solidly constructed buildings, and by the laws of chance it is unlikely that all would be hit. It will be objected that the sanitation would be difficult, but it could be improvised, as it had to be in field ambulances and casualty clearing stations in France.

Black Wednesday, September 28, is receding, and perhaps there seems an air of artificiality in discussing war measures now, but I have to admit that I was profoundly disturbed by our emergency arrangements. I have talked to many who, like myself, had front-line experience in the last war, and they think as I do. It was not only soldiers with whom we were concerned, but in the early days of the war we had to deal with large numbers of civilians of all ages—sick, wounded, and killed—and with women giving birth to children during bombardments, and the cry from the toughest men to the smallest children was always for cover. I cannot see the wounded content to be housed, even temporarily, say on the third or fourth story of a huge ferro-concrete building, a large area of the walls of which is composed of glass, even though it be covered by cellophane, brown paper, or three-ply wood.—I am, etc.,

London, N.W.1,
Nov. 23.

F. G. CHANDLER, M.D., F.R.C.P.,
Physician, St. Bartholomew's Hospital.

SIR.—I was very interested to read Dr. C. Watney-Roe's letter on bomb-proof shelters in the *Journal* of November 19 (p. 1064). Since May of this year I have been advocating bomb-proof shelters in Halifax as a *sine qua non* in any well-thought-out scheme of air raid precautions. Until such shelters are properly erected in sufficient numbers our people will continue to live in danger of mass slaughter. Improvisations are no use. The high-explosive bomb is a terrible weapon. The time has arrived—and it may be too late if we continue to delay in this matter—when every town should be provided with sufficient well-constructed bomb-proof shelters.

As regards first-aid posts, I am of the opinion that these, to be efficient, should be specially constructed. The adaptation of old buildings, schools, etc., will mean inefficiency, waste, and unnecessary loss of life. In view of the present very disturbed state of Europe—and the psychology underlying such disturbance—air raid precautions are likely to continue a permanent feature of our social structure. Of course the whole thing is a very sad commentary on our so-called civilization, but in the present circumstances it is our duty to give really adequate and efficient protection to our people. Half-measures will not do.—I am, etc.,

GEORGE C. F. ROE, M.R.C.P., D.P.H.,
Nov. 21. Medical Officer of Health, Halifax.

Food Supply in War Time

SIR.—In the Report of the Food (Defence Plans) Department for 1938 we read that "the experience of the great war shows that if control is to be effective in maintaining supplies and holding prices it must be introduced before and not after a shortage has arisen," but according to the figures given there is even to-day, before war starts, a serious shortage. In an article of mine in the *Medical Officer* (March 13, 1937), based on figures supplied by Viscount (then Mr.) Runciman as President of the Board of Trade, I pointed out that for everybody to have 5 lb. of flour a week (the amount stated as necessary by the National Dietary Committee) we need a total of 4,700,000 tons a year. The Food (Defence Plans) Department allows only 4,450,000 tons, and there are available only 4,450,000 tons yearly. If there is this shortage during

peace, how can we hope for satisfactory supplies during war? The amount of milk needed, as stated in the report, is 910,000,000 gallons, but the amount consumed to-day is only 785,000,000 gallons—or less than one-quarter pint a head daily—while 380,000,000 gallons go into factories at less than half the price which is paid by poor people for this essential protective food. It is stated under the heading of "other vegetables" that 2,425,000 are available. I have shown that if we allow only 1 lb. of green vegetables a head a week, which must be fresh so as to be "protective," we need a total of 900,000 tons a year. According to the figure given by the Food (Defence Plans) Department only 750,000 tons are produced at home, so that even during peace time there is a shortage.

The figures given by this Department also show that we produce only 8,000 tons of butter yearly, although 89,000 tons of cream are produced. The poor people get very little butter and they never get cream, so that the Food (Defence Plans) Department is going to maintain a supply of 80,000 tons of cream for the benefit of those who already are overfed. Is this a sane method of allowing the people to be fed? The A.R.P. arrangements have been shown to be anything but what they should be, but, alas! the Food (Defence Plans) Department arrangements are such as to reduce the people to a level at which no A.R.P. arrangements will be necessary!—I am, etc.,

Swansea, Nov. 19

G. ARBOUR STEPHENS.

Decline of Breast-feeding

SIR,—I was particularly interested in Dr. Horace A. Nathan's views (November 19, p. 1062) on the decline of breast-feeding. He states: "There are patients who, in spite of every encouragement, supplementary feeding, and all the other usually employed devices, prove themselves beyond any doubt incapable of supplying in the natural way any useful contribution to the baby's daily needs." (The italics are mine.) I think Dr. Nathan has indeed struck the nail on the head; for I contend that supplementary feeding is one of the chief causes of insufficiency of breast-milk, and is, in fact, one of the methods generally adopted when weaning is indicated. I am afraid that supplementary feeding is only too often advocated when complementary feeding should be the method of choice. Admittedly the terms "supplementary" and "complementary" are very confusing with regard to breast-feeding; but all textbooks teach that the supplementary feed is given to replace the breast-feed entirely for that particular meal, and that the complementary feed is given after the breast-feed to make up any deficiency in the mother's milk supply.—I am, etc.,

Southampton, Nov. 22.

S. CHALMERS PARRY.

SIR,—The address by Dr. J. C. Spence and the subsequent correspondence in the *Journal* prompt me to discuss a type of failure confined to a comparatively short period of the breast-feeding age—the failure which occurs in the first four weeks. Some time ago I undertook an investigation into the phenomenon, and it may not be outside the range of the present discussion if I quote the results of my inquiry and the opinions which, rightly or wrongly, I deduced from them.

During the investigation I found that in North Derbyshire 4.3 per cent. of the infants alive at 4 weeks had been completely weaned. Of those alive at 6 months 26 per cent. had been weaned. Of all weanings in the first six months in that area not less than 17 per cent. took place in the first month. In all I inquired into 100 cases of this type, eliminating all cases in which the weaning was brought about by some obvious reason such as the illness or absence from home of

the mother, illegitimacy, etc. I considered all the factors discoverable which might have had a bearing on the failure of natural feeding, whether affecting the mother or the infant; such conditions as, for instance, too frequent or irregular feeds, the state of nutrition and health of the mother, the condition of her nipples, the prematurity or immaturity of the child, and mechanical difficulties, such as hare-lip and cleft palate. The broad results of the inquiry are set out in the table.

An Analysis of One Hundred Cases of Failure of Breast-feeding in the First Month

| Primary Cause | Other Conditions Present | % |
|---|-----------------------------------|------|
| 33 Return to domestic duties | None discovered | 33 |
| 11 Ditto | Depressed nipples | 11 |
| 1 Ditto | Somnolence | 1 |
| 12 Ditto | Too frequent feeding | 12 |
| 2 Ditto | Mother undernourished | 2 |
| 2 Ditto | Mother ill | 2 |
| 1 Ditto | Weakling | 1 |
| 1 Ditto | Depressed nipples; weakling | 1 |
| 4 Nipple trouble—sore | | 4 |
| 6 Ditto—depressed | | 6 |
| 3 Exudative diathesis (dyspepsia) | | 3 |
| 1 Mother undernourished | | 1 |
| 2 Mammary abscess | | 2 |
| 1 Birth injury to child | | 1 |
| 7 Weakling | | 7 |
| 2 Ditto | Depressed nipples | 2 |
| 2 Cleft palate | | 2 |
| 9 Bad management during lying-in period | | 9 |
| 100 | | 100% |

In thirty-three instances the milk had been well established while the mother was confined to bed, all conditions for suckling were favourable, there was no apparent reason for weaning, but the milk became scanty when the mother got up and weaning followed. In thirty other cases there were various conditions present which might have influenced the issue to some extent, but in my opinion none of these were grave enough in themselves to have caused failure, and in all of these cases breast-feeding had been quite satisfactory up to the time when the mother left her bed. In the remaining thirty-seven cases there were obvious troubles, as set out in the table, which in the majority of instances were probably the primary causes of the failure. It will be apparent, however, that even among this group of thirty-seven there were a considerable number in which weaning need not have taken place, if only the difficulty had been taken in hand soon enough and energetically enough; the ten cases of nipple trouble, for instance, and the nine cases of "bad management," by which I mean lack of will to nurse, or lack of perseverance, or unwise advice given by relations or friends. Probably, too, the nine "weaklings" could have been successfully breast-fed if dealt with in a hospital or institution.

The really significant group, however, is the sixty-three at the head of the table. Why did failure occur in these cases? Nipple trouble had little or no effect during the first fortnight, too frequent feeds had no material influence, nor had the condition of the mother as to health or nutrition. Yet at the end of the month all had been weaned. In the words of the mothers themselves, "the milk went when I got up." Why? Should the mother have stayed in bed a little longer and had more rest? One case, included in the table, and two others, not included, are significant. In one the mother lay in bed twenty-three days owing to a post-partum haemorrhage; during this period, suckling was thoroughly satisfactory. Directly she got up her milk became scanty. In another case the woman was confined while away from home with friends. She remained away five weeks, during which time her milk was ample and the baby thriving. On her return home the milk at once faded away. In the third case the mother lay in bed six weeks with phlebitis. The child was quite satisfied during this time and put on weight, but as soon as the mother got up and resumed domestic duties the child became uneasy and dissatisfied. Supplementary feeds were begun and weaning ensued.

Three cases of depressed nipples are instructive. I found that while in bed there was plenty of easily flowing milk, and

the infants secured enough for their needs. Directly the mother left her bed the flow became less free and the infants were "suffocated" in their efforts to get a firmer grip of the nipple. In all these sixty-three cases there is only one common factor—the rising from bed and, with it, the resumption of domestic duties and anxieties. I formed the opinion that this was the decisive issue, though helped, no doubt, in some cases by auxiliary factors, in bringing about the early weaning.

The fact is that efficient motherhood is almost, if not quite, a whole-time job. Anything that diverts the mother's energies from the strict business of nursing her child, whether it be the mental and physical strain of the working-class woman returning to domestic duty or the social engagements of the more leisured classes, will detract from the continued efficiency of the maternal function. It is largely a psychological problem. I have formed the opinion that this early failure occurs more often in the anxious, highly strung woman than in the woman of the stolid and phlegmatic type, in the "Marthas" of modern life, "careful and troubled about many things," rather than in the idle and less caring. The feckless and the slattern can feed successfully in almost any circumstances and up to almost any period. In short, it is the best type of womanhood who most needs our help and consideration at this critical period.—I am, etc.,

H. W. POOLER, M.B.,

Ashover, Nov. 24. Medical Officer to Child Welfare Centres,
Derbyshire County Council.

REFERENCE

Brit. J. Child. Dis., 1930, 27, 269.

SIR.—After conducting four infant welfare centres weekly for ten years, may I contribute the following observations on breast-feeding? In my experience breast-feeding is a function of the endocrine system, and as such is largely beyond our scope—some women successfully breast-feed all their babies without any trouble, others never achieve it. It is much more than a question of adequate diet. One woman feeds herself on the ideal diet, grows fat, and has a thin inadequate milk supply. Another woman is palpably underfed and successfully suckles a lusty baby. I often get mothers to put their babies to the breast at the clinic, and to see the half-starved infant trying to avoid the nipple, taking a few despairing pulls at it, and then bursting out into cries of rage, convinces one that in these cases the psychological benefits of breast-feeding are *nil*, and that the game is not worth the candle. I give the mothers a pamphlet on breast-feeding; I suggest, and often supply from the clinic, lactagol, calcium and iron tablets, free milk, etc.; but I find that if the milk supply has begun to fail these things seldom restore it. This may be a confession of failure, but it is my experience. The successes of such places as the Mothercraft Training Centre, where mothers and babies are admitted and breast-feeding re-established, are not reproduced in the ordinary conditions of clinic work. I should say that not more than 50 per cent. of our mothers, leading a poverty-stricken, working-class, town life, are able to breast-feed; I should say also that 99 per cent. of them would like to breast-feed, and that all those who do so successfully enjoy doing it.

Fortunately these views are not so gloomy as might be supposed, for I would defy any doctor given a hundred children of 1 year of age to examine to pick out those who had been breast-fed and to be 100 per cent. right. I endeavour to examine all babies under my care on their first birthday, and I do not find any marked difference between naturally well-fed babies and artificially well-fed

babies, using such criteria as closure of fontanelle, number of teeth, firmness of limbs, etc. The same thing applies in the examination of 5-year-olds at their school entrance examinations; the exceptionally well-developed child has by no means always been breast-fed.—I am, etc.,

Bournemouth, Nov. 26.

GRACE H. WOOD.

Prevention of Breast Infection

SIR.—Breast abscess may also arise through massaging the breast with undue heaviness and thereby bruising the tissues. This may explain an apparent epidemic in an institution, the probationers being insufficiently supervised. I have just dealt with two such abscesses of contusion: one followed excessive massage, the other recurrent strenuous efforts to get a retracted nipple into the baby's mouth by compressing the breast surrounding the nipple with the fingers.—I am, etc.,

Birmingham, Nov. 20.

W. J. BURNS SELKIRK.

Mental Treatment Services

SIR.—A perusal of the Board of Control's *Annual Report for the Year 1937* (a précis of which appears in the *Journal* of November 12 (p. 1006)) gives rise to the reflection that, though in many respects an enlightened and illuminating publication, it is, with respect to a number of matters, apt to give a misleading impression.

1. The Board criticizes the development of out-patient centres on the ground that the function of many of these centres is mainly diagnostic. While with regard to out-patient centres organized in association with mental hospitals this may be true, it must not be taken to speak for the country as a whole. In Liverpool, for example, the Board can only speak for three of the ten psychiatric out-patient clinics in existence in the city. At two of the voluntary clinics—the Liverpool Psychiatric Clinic and the Department of Psychological Medicine of the Liverpool Royal Infirmary, both clinics at which patients are seen regularly for treatment—there were dealt with during the twelve months ended March 31, 1937, 496 new patients, total attendances numbering 3,446. The corresponding figures for the three clinics associated with the local mental hospitals were: new patients 181, total attendances 1,445. Comparisons are odious, but these figures are quoted solely for the purpose of suggesting that, in one area at any rate, the picture is not quite so discouraging as the Board's report would have us suppose. Moreover, during the year ended December 31, 1937, the volume of work dealt with by the two clinics referred to above was almost double that for 1935, amounting to 602 new patients and 4,428 total attendances.

2. Allusion is made to the difficulty of staffing such centres, and the St. Albans Clinic is cited as an example of how psychotherapists in outside practice have been employed. While it is only with the greatest hesitation that one would claim sufficiency in number of staff in a rapidly growing clinic, it is notable that the Liverpool Psychiatric Clinic (founded so comparatively long ago as 1924) has a medical staff of six persons—three men and three women; and with regard to the Board's statement that "... if centres continue to be staffed insufficiently or by doctors who have to give up (as many do) part of their leisure to out-patient work, there can be little hope of improvement in this direction," it should be pointed out that of these six medical officers one only receives part-time remuneration, the services of five being rendered voluntarily. It is felt very strongly that the Board of

Control could play a valuable part in encouraging co-operation between the various services dealing with mental treatment. A natural reply to this suggestion is that this is a matter for the locality concerned, but on reflection there will perhaps be realized the obvious difficulties that are apt to arise, difficulties that are more easily overcome if assistance and guidance come from a central and, so far as the locality concerned therefore an independent, body or authority such as the Board.

3. The report states: "To start a private practice in psychiatry to-day outside of London is a hazardous adventure. It is not surprising that, except in London, there are lamentably few private practitioners in this branch of medicine. . . ." While it may be admitted that relatively the number of psychiatrists practising privately is all too few, it might be pointed out that there are in this city no fewer than ten fully accredited specialists whose practice is devoted to psychological medicine. Five of these have been in whole-time psychiatric practice for periods of twelve to fifteen years. It is, therefore, not altogether a shortage of those who will dare "the hazards and prizes of private practice" that is the difficulty so much as a lack of disposition on the part of those concerned to encourage co-operation with psychiatrists, however qualified and experienced, who are not members of the mental hospitals service.

I do not speak for the governing bodies of the clinics to which I have referred, and this is but a personal view, but it has seemed to me that it would be most undesirable in relation to psychological medicine for there to occur between official treatment services on the one hand and voluntary and private effort on the other that cleavage which long ago occurred in the hospital services devoted to physical medicine—a gap which it has proved so difficult to bridge. It would seem unfortunate if, at this comparatively early stage, the opportunity for greater co-operation should be lost.

Finally, and with the utmost respect, it is submitted that before generalizing with regard to conditions of treatment service and of psychiatric practice, attempting to speak for the state of affairs as related to the country as a whole, or authorizing the establishment of new centres, the Board of Control should acquaint and familiarize itself not only with the facilities and centres directly associated with the institutions under its supervision but also with the work that is going on outside its immediate purview. It may be argued that these efforts are no concern of the Board's, but that is also an argument against the issuing of general statements which do not give an accurate presentation of the facts.—I am, etc.,

Liverpool, Nov. 21. S. BARTON HALL, M.D., D.P.M.

The Occipito-posterior Case

SIR,—Although I do not agree with much of what Dr. David Price says (*Journal*, September 17, p. 638), I do agree with him that when the head (in the occipito-anterior position) has become fixed or impacted behind a partly dilated cervix it is so difficult for further dilatation to take place as to interfere seriously with the progress of labour. In fact, this condition has been the commonest cause of protracted labour in my experience. Here also I must agree with Dr. Price in that I consider that the application of forceps through the partially dilated cervix is the treatment of choice. We get remarkably few cases of persistent occipito-posterior presentation in this part of the country, so that I am speaking of cases of occipito-anterior presentation only. The usual case has proceeded normally but slowly until this stage is reached, and then,

in spite of strong pains, no further progress is made. The pains begin to diminish in frequency and severity, and the case is further protracted by secondary uterine inertia. On vaginal examination one can feel a substantial rim of cervix all round the head, and this is often after several days of strong labour. If forceps are now applied and, with a finger in the vagina carefully gauging the tension on the cervical rim, traction is exerted, it will be found that a considerable force has to be used to get the head to move. Once on the move, however, my practice is to remove the forceps, and I find that the pains soon come back, the cervix dilates rapidly, and the foetus is speedily delivered with remarkably little trouble.

If it were more generally realized that the commonest cause of slow dilatation of the cervix is not rigidity but impaction of the head in the middle of the birth canal, the conservative use of forceps in this way would be an everyday matter and not a cause of horror, as it seems to be. After all, the country practitioner is now, as he has always been by force of circumstances, the acknowledged expert in cases which without being abnormal are really difficult.—I am, etc.,

W. H. M. WILSON.

Burnham-on-Crouch, Essex, Nov. 19.

Adrenaline Treatment of Asthma

SIR,—May I refer to some points raised by the correspondence on the above subject.

The effect of injecting adrenaline is purely physiological. It evokes all the phenomena normally evoked by stimulation of the sympathetic system, including active dilatation of the bronchi and bronchioles. In allergic asthma the condition is one of vagotonia, and it should be remembered that many such patients have a low blood-pressure and some degree of hypoglycaemia.

The effect of an injection of, say, 0.5 c.cm. of a 1:1,000 solution of adrenaline in a healthy individual is to produce an *appearance* of fright or disturbed emotion in the absence of *real* fright or emotional disturbance; that is to say, pallor, dilated pupils, "startling eyes," dry mouth, goose-flesh, quick, deep breathing, with increased secretion of urine. Emotional disturbances are *par excellence* the common stimuli which cause the adrenal glands to become active and, through their hormone, the appearance associated with the corresponding emotion. Plentiful reserves of sugar are poured into the blood and the bronchi are dilated, so that the individual is in a state of mobilization, instantly ready to fight or fly. It is not unusual to find that a sudden access of temper occurring on the inception of an attack is sufficient to provide adequate stimulation of the adrenals and that the paroxysm does not materialize or is aborted. When adrenaline is injected in asthma we are not supplying a deficiency directly but merely stimulating the sympathetic system generally and through it the adrenals, which provide their own adrenaline. The injection is merely the detonator, or the pinch of powder on the touch-hole of an old-fashioned cannon. Bronchospasm is an indication of vagotonia or vagosympathetic imbalance. The injection adjusts it and brings about a temporary sympathotonia.

I have never seen the symptoms mentioned by Dr. Joah Bates (*Journal*, October 29, p. 921)—continuous dyspnoea and cyanosis—in a patient with allergic bronchospasm and a normal circulatory system, in spite of the fact that post-mortem records show that approximately one person in three has some form of patent interauricular communication. Such symptoms would suggest to me an underlying abnormality in the circulatory system.

It should not be lost sight of that in persons who have never had a typical paroxysm of asthma some degree of spasm of the smaller bronchioles is not infrequently found, the only complaint being of "chestiness."

I have always found it preferable to give a small dose of adrenaline at the earliest possible moment, if necessary self-administered by the patient himself. In this way 0.2 c.cm. may suffice. It has been my experience that the longer one can ward off a fully developed paroxysm the less likely the patient is to have one. I have never seen pulmonary congestion or cardiac failure, or for that matter arteriosclerosis, after long-continued use of adrenaline in a patient with a normal circulatory system. As regards pulmonary congestion, is not adrenaline actually useful as a haemostatic in haemoptysis?—I am, etc.,

Brookwood, Surrey, Nov. 25. H. M. STANLEY TURNER.

SIR,—When I mentioned 60,000 injections I was relying on the patient's own statement. He was a highly scientific man and I had no reason to doubt his figures. He had his first attack of asthma in the night after some polypi were removed, and he subsequently used adrenaline by injection for over twenty years. I first saw him in 1907 when he had had asthma for three years, which had been made progressively worse by further operations for the removal of polypi and clearing of the ethmoidal cells.

For perhaps some eight or nine years I was able to restrain him from having more polypi removed, and he was able to exist in a fair amount of comfort with three or four injections of adrenaline a day. Then an eminent rhinologist undertook to cure his asthma by a further nasal operation. The patient asked my advice, and I told him that I was anxious not to interfere with the prospect of his obtaining relief but that I believed the operation would increase his daily injections of adrenaline from three to five. My surmise was not altogether correct, for after the operation he needed eight injections a day. The rhinologist was confident that another operation would cure him completely; this was done, with the result that the daily injections went up to twelve. Some time later the rhinologist discovered yet another polypus and persuaded the patient that this was the sole remaining cause of his asthma. His distress by this time had become so acute that he allowed this to be removed, and subsequently he required twenty injections a day to enable him to breathe.

Ever since 1903 I have issued warnings against the indiscriminate removal of nasal polypi in asthmatic cases. In the *Journal* of August 29, 1925, I wrote: "If operators could see some of the many patients who come to me who have been made helpless asthmatic wrecks by nasal operations for the removal of polypi they might possibly pause and think." In a paper in the *Practitioner* of September, 1929, Dr. Clement Francis clearly discussed the question of when to remove polypi in asthmatic cases. Yet some rhinologists will not realize that it is disastrous to remove polypi by extensive operation from aspirin-sensitive patients, especially when the blood pressure is low. I wish Mr. Hutchinson could suggest some method of giving relief to a patient who has had a submucous resection of the nasal septum, complete removal of polypi, free drainage of the ethmoidal cells and antra, in addition to allergic tests and treatment including living in a dust-free atmosphere; and who now needs to be continually under the influence of adrenaline, which at times gives little more than temporary relief. I know other cases whose present desperate condition is, I maintain, due to their having had nasal polypi removed when they were aspirin-sensitive.—I am, etc.,

London, W.1, Nov. 27.

ALEXANDER FRANCIS.

Artificial Anterior Pneumomediastinum

SIR,—I would like to correct a false impression which may be created by your reference in the annotation on extra-pleural pneumothorax (*Journal*, November 19, p. 1050) to a paper of mine on artificial anterior pneumomediastinum (*Post-grad. med. J.*, 1938, 14, 216). In that paper I believe I was more cautious than appears from your reference in assessing the value of artificial anterior pneumomediastinum as an agent of collapse therapy, and I emphasized that it is not intended to replace artificial pneumothorax. When this is not possible and the lesion is moderately recent and situated in the anterior and paramedian aspect of the lung, I believe that artificial anterior pneumomediastinum should be given a trial. An incitement to research with this new procedure is very different from a recommendation of its more or less indiscriminate application, which was never in my mind.

I would like also to lay stress on the fact that the procedure was intended by its originator, Professor Condorelli, to serve as an aid to the diagnosis of conditions affecting the pericardium and the mediastinum, with special regard to pleuro-pericardial and pericardio-sternal adhesions. Its diagnostic value is, to my mind, quite well established, and has been confirmed at the Italian Hospital in a recent case. In this the skiagraphic demonstration of air between the sternum and the heart and in the pleuro-pericardial spaces, after the introduction of 200 c.cm. of air into the anterior mediastinum, excluded the clinical diagnosis of adhesive pericarditis and saved the patient from an unnecessary operation. I would like to add that no untoward effects were observed in this patient.—I am, etc.,

Italian Hospital, London, W.C.1. E. MONTUSCHI, M.D.
Nov. 22.

The Blood Platelet

SIR,—The routine examinations of the blood I have been accustomed to make, which include the use of the dark-ground condenser, have led me to conclude that blood platelets are agglutinated colloid (protein) particles.

Employing the terms to which I am used, agglutination is a stage of dehydration which separates this chemical-physical change from the one of hydration. Any agent which dehydrates the colloid particles in the blood, which are mainly protein in nature, tends to increase the number of the platelets, whereas the production of hydration has the reverse effect. In citrated, oxalated, or heparinized blood, provided sufficient hydration has been produced, no platelets are to be found in the plasma which is examined with a dark-ground condenser. But when a calcium salt, which dehydrates these hydrated colloid particles, is allowed to reach the plasma under the cover-slip, platelets of varying shapes and sizes appear in abundance. The significance of the presence or absence of platelets as an isolated observation is nil.—I am, etc.,

London, W.1, Nov. 25.

J. E. R. McDONAGH.

Grenz-ray Therapy

SIR,—I was interested to note the annotation in your issue of November 26 (p. 1093) on Grenz rays. In co-operation with Bucky I have investigated the influence of these rays in a number of constitutional diseases. It is impossible to discuss results in a letter, but it is perhaps of interest to mention that very good results have been achieved in previously intractable cases of bronchial asthma and in certain forms of arthritis. I quote these

two diseases as you referred to them specially in connexion with Scott's work. This author, working with deep x rays, has shown that medium voltage, comparatively large field, and small dosage should be applied to indifferent areas of the body. Similar principles are applicable in Grenz-ray therapy, but instead of 100-150 kV it is the practice to apply 10 kV with consequently very greatly reduced x-ray energy.

I welcome the suggestion advocating a controlled investigation of the effect of Grenz rays in various constitutional diseases. This method of treatment is without danger and is simple to carry out. Further, the method is economical in use, and this is a factor of particular importance in considering the application to any large-scale investigation. Though it is possible to point to more than 1,000 references in the literature of Grenz-ray therapy there are as yet but few publications dealing with this treatment in constitutional diseases. Further work in this direction is certainly indicated.—I am, etc.,

London, W.1, Nov. 27.

Z. A. LEITNER.

Control of Small-pox in India

SIR.—Although the infectivity of variola minor is low, Dr. C. Killick Millard is not correct in his statement that it is not infectious, nor, indeed, is it an entirely harmless disease. In "A Critical Review of the Clinical Features of 13,686 Cases of Small-pox" (variola minor), Dr. J. Pickford Marsden (L.C.C., 1936, No. 3,209) reports that three cases were toxic and nineteen confluent, while the total number of deaths was thirty-four (0.25 per cent.). Among these deaths small-pox was the direct cause in five, the immediate cause in eleven, a definite contributing factor in three, and a remote contributing factor in fifteen. Complications are also not unknown in variola minor similar to, if not so frequent as, those found in variola major, such as subcutaneous abscesses, encephalomyelitis, and various ocular complications, as shown by Dr. C. R. M. Greenfield, who reported 218 cases (3.4 per cent.) among 6,233 small-pox patients admitted to the river hospitals of the L.C.C. in 1930 (Ann. Rep. L.C.C., 1930, 4 (Part III), 174.—I am, etc.,

London, W.8, Nov. 25.

J. D. ROLLESTON.

SIR.—While agreeing with Dr. C. Killick Millard (November 19, p. 1061) that the mortality from small-pox in India is appalling, I cannot agree with the measure he propounds to combat it. I do not propose to discuss the merits or demerits of his suggestion, but merely the practicability of introducing it into that country. My experience of the various sects in India, and having had to deal in an administrative capacity with outbreaks of 5,000 (registered) cases annually, and smaller outbreaks elsewhere in India, convince me of the danger of the suggestion. When a certain sect, at the worst stage of the disease, wishing to appease the evil spirit (or the goddess Mithra) gathers a party of the relatives—men, women, and children, perhaps all unvaccinated—around the confluent case of small-pox, how on earth can one prevent the spread of the disease when many will not even hear of being vaccinated? I have seen this often. Not only this, but they will often block up the small inlets for ventilation (apologies for windows) to propitiate the evil spirit. In such places there are large groups of people living one above the other and perhaps on the same storey. Many of the leaders of the sects, and even some active practitioners, have no faith in vaccination. I have often been able to persuade (the work is really

a missionary effort) early infected cases to be vaccinated, with a modification of the disease and saving of life. Again, not only are these houses infected—and their construction makes practical disinfection an impossibility—but often the clothes of the deceased patients are sold, and the clothes of vaccinated contacts will still carry the disease.

The first line of defence, in my opinion, is education of the leaders of the people as to the value of vaccination. With a view to enlightening these leaders—often on municipal bodies—in sanitary matters and public health generally, I started the *Indian Public Health and Municipal Journal*; the various municipalities took this journal and the local Governments subscribed for certain copies for distribution. Keener insight is now being shown in sanitation, but there is much to be done owing to the stupendous problem of fighting against religious views and ignorance. There is no evidence that vaccination has lamentably failed in India. On the contrary, where vaccination has been used the statistics show its great value.

Now, what would be the effect of introducing inoculation with the virus of variola minor in place of vaccination with calf lymph? In the first place, it would mean making a new start and undoing the past education and belief in vaccination, and all that has been gained by it under difficulties. Dr. Millard now proposes to tell the people that doctors are actually going to produce in them a mild type of small-pox so that they may be protected against a severe type. Not only would this be "handing the torch" to others, so far as the disease is concerned, but agitators would say, "The British Government is producing a loathsome disease among the people and many of our children will die of it." It would be dangerous to give them such an argument, and the administrative difficulties would be enormously increased. We cannot afford to try the experiment in India, as variola major would still exist and its existence to any larger degree would be put down to the experiment. Why not leave well alone and continue the education of the leaders and all medical men in India as to the value of vaccination. The people are coming to recognize its value; why break this trend?—I am, etc.,

Ilford, Nov. 21.

A. G. NEWELL, M.D., D.P.H.

SIR.—Dr. C. Killick Millard's statement in his letter in the *Journal* of November 19 that vaccination in India has been "a lamentable failure" cannot be allowed to pass unchallenged. Far from being a failure, the success of vaccination will not be disputed by any medical officer who has served in India. May I inquire if Dr. Millard has any experience of India? Also, how many of the deaths he quotes from the statistics in Bengal were among vaccinated people? Statistics may prove anything, especially in India. The registers of births and deaths in the villages are kept by the village watchmen, who are mostly illiterate, and therefore the records of the causes of death are very unreliable. All cases with a pustular eruption would be entered as small-pox. I am of opinion that if vaccination were made compulsory small-pox would soon be stamped out. During my service in the Punjab as regimental medical officer and civil surgeon I have never seen a case of small-pox in a properly vaccinated person—that is, one showing three good marks on each arm. Small-pox is unknown in the Indian Army and the Police Service, where vaccination is compulsory. The Punjabi woman realizes the value of vaccination, and will bring her infant from outlying hamlets two or three miles for vaccination and inspection.

tion. A great deal depends upon the proper supervision of the vaccination staff and the help given by the local notables and headmen of villages. Certainly vaccination in the Punjab is anything but a failure.

Possibly political reasons—which I need not specifically explain but which will be understood by anyone with Indian experience—have led to laxness in vaccination in Bengal. If the work of the vaccinators is not properly inspected one cannot expect to have good results. When I was a civil surgeon I had to inspect the vaccination, and I always found the work was good and failures were extremely few. In my time it was common to see elderly Indians pock-marked; but it was rare to see Indians under 30 marked at all. I can only answer for my own province; but from what I have seen there I can entirely refute Dr. Millard's statement.—I am, etc.,

H. C. KEATES,

London, S.W.16, Nov. 23. Lieutenant-Colonel I.M.S. (ret.).*

R.M.B.F. Christmas Gifts

SIR,—We have the following letter to our beneficiaries ready for dispatch, printed with suitable decoration in red and green:

Christmas Greetings from the Royal Medical Benevolent Fund.

Dear —,

Many supporters of the Royal Medical Benevolent Fund have kindly subscribed to a Special Fund which enables the Committee to send you the enclosed Christmas Gift of thirty shillings.

We all hope that the Gift will contribute to your happiness, and it brings from many friends Christmas Greetings and Good Wishes for the New Year.

With kind regards,

Yours very truly,

Unfortunately, Sir, we have not yet received sufficient response to my appeal to enable us to send the thirty shillings to all our beneficiaries. May I ask your readers who have not responded to my letter which appeared in your paper during the month of October to send a donation as soon as possible so that we may make the distribution in proper time. Contributions, large or small, will be gratefully received by the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, London, W.1.—I am, etc.,

THOS. BARLOW,

President.

Nov. 30, 1938.

The Services

RHEUMATISM RESEARCH: NAVAL TRAINING CENTRES

It is announced by Lord Horder that the Empire Rheumatism Council, in co-operation with the Admiralty, has set up a Research Foundation to investigate the causes and the best means of prevention and treatment of rheumatic disease in the training establishments of the Royal Navy.

The history of rheumatic disease in the Navy in recent years shows that up to the first decade of this century rheumatism was a considerable problem in H.M. ships. It is now rare among trained seamen; the success in overcoming it is probably due to the improvement of medical services and living accommodation. In the training establishments, however, the position cannot yet be considered entirely satisfactory, and the Medical Service of the Admiralty and the Naval Medical Staff, hospitals, and laboratories will assist the Empire Rheumatism Council Research Foundation in its investigation in every way possible. The Empire Rheumatism

Council recognizes the importance of the task, not only as a service to the principal line of defence of the realm, but as a highly promising opportunity of solving one of the chief problems of the causation and treatment of rheumatic disease, since there will be opened up a wide field of research among a great number of youths, all of the same age-group, all under disciplinary control and subject to medical observation over a long period. Accordingly it will enlist to the fullest necessary extent its scientific resources for this Research Foundation.

The Research Advisory Committee has appointed an *ad hoc* subcommittee, consisting of Lord Horder, Sir William Willcox, Professor Geoffrey Hadfield, Dr. Mervyn Gordon, and Dr. W. S. C. Copeman, to supervise the work generally. Dr. C. A. Green comes from the Bacteriology Department of Edinburgh University to take direct charge of the Foundation; the Sir Halley Stewart Trust has granted him a Research Fellowship for three years for this task, and he will be assisted by other permanent workers as and when found necessary. Every factor in the problem—bacteriological, biochemical, and environmental—will be investigated at the chief naval training establishments.

DEATHS IN THE SERVICES

Surgeon Captain KENNETH HURLSTONE JONES, R.N. (ret.), died at Canterbury on November 15, aged 65. He was educated at Owens College, Manchester, and graduated M.B., Ch.B. at the Victoria University in 1897. He entered the navy immediately afterwards, became fleet surgeon on November 29, 1911, and retired with an honorary step in rank as surgeon captain on January 1, 1924. He served throughout the war of 1914–18, receiving the medals. He received the honours of Officer of the Order of the Crown of Belgium and Commander of the Order of St. Stanislaus (with Swords) of Russia, and was surgeon to the Canterbury Corps of the St. John Ambulance Brigade. In 1905 he contributed an article to the *British Medical Journal* on a case of primary sarcoma of the lung, and four years later one on the birds of Wei Hai Wei. He had been a member of the British Medical Association for thirty-nine years.

Universities and Colleges

UNIVERSITY OF OXFORD

On January 1, 1939, Dr. B. G. Macgregair will succeed Dr. K. J. Franklin as Dean of the Medical School.

UNIVERSITY OF CAMBRIDGE

The Faculty Board of Medicine has appointed Dr. T. S. Hele (Master of Emmanuel College), Dr. G. S. Graham-Smith, F.R.S., and Mr. W. H. Bowen to be members of the M.D. Committee for the year 1939; and Dr. W. L. H. Duckworth to be an Awardee of the Marmaduke Shield Scholarship.

Applications for a John Lucas Walker Studentship should be sent before December 10 to Professor Dean, at the Department of Pathology, to whom requests for further information regarding this studentship may be addressed. It is tenable for such period, and will be of such annual value not exceeding £200, as the Professor of Pathology with the approval of the Managers may determine.

J. B. Watson has been approved at the examination for the Diploma in Medical Radiology and Electrology.

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—*With Special Knowledge of Mental Diseases*: H. N. Bradbrooke, J. E. O'N. Gillespie, D. Gilmour, J. B. Phillips. *Part A*: R. W. Crockett, M. S.-M. Rayner.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have satisfied the examiners at the examination indicated:

MASTERY OF MIDWIFERY.—John Desmond Burrows, M.R.C.S., L.R.C.P., Margaret Stewart Lithgow McCash, M.D., Sherda Shrinivasu Naidu, M.B., B.S., D.T.M. and H., Achamma Thomas, L.M.S., L.A.H., D.C.H.

to the building of houses by alternative methods of construction, which made the minimum demand on the types of labour that were short and made the most use of the types of labour that were plentiful. This policy was being further developed by this Bill. At the same time the Government did not regard these alternative methods as anything more than a supplementary way of providing houses, and expected local authorities to push on with all possible speed with building by ordinary methods.

The Bill was read a second time.

Unhygienic Conditions in Ships

On November 22 Mr. BEN SMITH asked the President of the Board of Trade whether his attention had been drawn to the annual report of the Tyne Port Health Authority for 1937, which stated that the inspection of vessels revealed 1,691 defects, many of them concerned with heating, doors, floors, bunks, lavatories, dampness due to leaking decks, ports, skylights and decklights, the presence of dirt, vermin, litter, discarded bedding, and the need for painting; and whether, in view of the fact that many of these defects remained unremedied, he would take steps to ensure a stricter adherence to principles of comfort and hygiene. Mr. OLIVER STANLEY said the port health authorities had full powers under the Public Health Acts to require the abatement, or themselves to abate, in ships within their districts insanitary conditions or other nuisances injurious to health. The duty of seeing that crews' quarters were kept in a fit condition fell primarily on the master as representative of the owner. A joint committee set up by the Shipping Federation and the National Union of Seamen was at present considering methods of improving the standard of comfort and cleanliness in crews' accommodation. Close co-operation was also maintained between officers of port health authorities and Board of Trade surveyors.

Medical Service of Dependants in Scotland

On November 22 Mr. WESTWOOD asked the Secretary of State for Scotland if he had considered the report of the Departmental Committee on the Scottish Health Services, with special reference to the provision of a medical service for wives and dependants of insured persons, and what action, if any, he proposed to give effect to either the majority or minority reports. Colonel COLVILLE said that this matter had received careful consideration, but he could not at present hold out any prospect of legislation.

Mr. WESTWOOD asked if the Minister was aware that the section of the British Medical Association which represented Scotland was now unanimous that some action should be taken in the interests of the health of the dependants of insured persons in Scotland. Colonel COLVILLE said he was aware of the importance of the question. The committee found it difficult to arrive at a solution.

Pulmonary Disease Investigation in South Wales

Earl WINTERBURN, replying to Mr. J. Griffiths on November 22, said that the investigation into chronic pulmonary disease among coal-miners in South Wales was making good progress. The analysis of the large amount of evidence collected at the Ammanford No. 2 colliery had been completed. As a result, it had been decided not to make another comprehensive study of this kind, but to make more limited and rapid inquiries at a number of different pits which were now being selected. It was hoped to complete these further inquiries within six months, but as the results could not be foreseen it was not yet possible to say when the investigation as a whole would be concluded.

Hospital Superintendents and Matrimonial Causes Act

On November 22 Mr. SORENSEN asked the Minister of Health whether he was aware of the difficulties that had arisen in connexion with the Matrimonial Causes Act through the failure or refusal of a mental hospital visiting committee to safeguard a medical superintendent by giving him instructions on the answering of reasonable inquiries respecting divorce proceedings; and whether he would take steps to avoid any

such difficulties in future. Mr. BERNAYS said that the Board of Control had suggested to the Mental Hospitals Association that the position of the medical superintendent might be safeguarded if the visiting committee gave him definite instructions to answer reasonable inquiries. The Minister of Health was not, however, empowered to give visiting committees any direction in this matter.

Government and Treatment of Cancer

Dr. ELLIOT was asked whether, before establishing further centres for the treatment of cancer by radium, he would have an expert investigation made of the whole question of radium treatment. He replied on November 24 that the further centres proposed to be established were for the treatment of cancer not merely by radium but by every recognized therapeutic agency. Radium was generally agreed to be a valuable agent in the treatment of cancer, in spite of the dangers attending its unskilful use. He did not think that the establishment of more centres should be deferred on that account.

Defective Hearing in Children

Mr. DAVID ADAMS asked on November 24 what steps the Government proposed to carry out the recommendations of the committee of inquiry into problems relating to children with defective hearing, and, in particular, if steps were being taken for the establishment of schemes for the treatment of ear diseases and defective hearing as a branch of the school medical service of local education authorities. Mr. KENNETH LINDSAY replied that the Board of Education was in general agreement with the recommendations of the committee, and was considering what steps were necessary to give effect to them. About one-half of the local education authorities were known to have schemes for the treatment of ear diseases and defective hearing. These schemes comprised arrangements either for the services of visiting specialists at aural clinics or for the provision at hospitals of in-patient or out-patient treatment.

Refuse from Coal Mines

Mr. J. J. LAWSON moved on November 25 the second reading of the Public Health (Coal Mine Refuse) Bill. He said the Bill was to make automatic instead of permissive the obligation to deal under Section 92 of the Public Health Act, 1936, with accumulations or deposits of refuse from coal mines if liable to spontaneous combustion. Such accumulations would be deemed to be prejudicial to health or a nuisance. Sir FRANCIS FREMANTLE said the nuisance clause of the Public Health Act had been a subject of contention ever since it was enunciated in the Act of 1875. It was difficult to say what was prejudicial to health or a nuisance.

Mr. BERNAYS said he was not convinced that the Bill would do all that was expected of it, but the House should give it a second reading.

The Bill was read a second time.

Health Insurance for Dependants.—Dr. ELLIOT holds out no hope of introducing legislation at present whereby the wives and children of persons insured under the national health insurance scheme may become entitled to medical benefit under the panel system.

Non-pulmonary Tuberculosis in Lancashire.—Mr. RHYS DAVIES asked, on November 10, whether the last annual report of the county medical officer for Lancashire showed increases in the number and percentage of non-pulmonary tuberculosis cases among children; if so, how these figures compared with other industrial areas. Dr. ELLIOT replied that there was a certain increase in the number of cases of non-pulmonary tuberculosis notified, consequent upon the medical examination of the school children, but the annual report of the county medical officer did not indicate any increase in the total number of cases among children. Indeed the figures showed a slight decrease compared with the preceding year. For the country as a whole there was a slight rise in the notifications of deaths at all ages. For Lancashire the figures were rather more favourable.

Investigation into Causes of Rheumatism.—Mr. WHITELY on November 17 asked Dr. Elliot to consider the advisability of setting up a committee of inquiry into the causes of rheumatism with a view to its cure and prevention. Dr. Elliot replied that research into the problem of rheumatism was already undertaken by the Medical Research Council as part of its general activities. Investigations were also in progress by the Empire Rheumatism Council. It would be undesirable at present to institute another inquiry.

Fumigation with Naphtha Vapour.—Dr. ELLIOT, replying to Mr. Kirby on November 17, said the corporation of Liverpool among other methods of disinfection used naphtha vapour gas. In one case where there were special circumstances a claim made by an occupant of a neighbouring house for injury to health through the escape of naphtha fumes was settled out of court by the corporation. Such few other complaints as had been made had not been substantiated, and no danger to health need be apprehended. The control and management of houses belonging to local authorities were vested by statute in the authorities, and he had no power to give them instructions to arrange the evacuation of adjoining property while disinfection was taking place. The safest and most effective way of removing vermin from dwelling houses was under the consideration of a committee of the Medical Research Council.

Sewage Disposal in Holiday Camps.—Mr. POOLE asked on November 17 a question alleging unsatisfactory sanitary arrangements during the past summer in holiday camps in the urban district of Abergele. Dr. ELLIOT replied that representations had been made to him on the method of disposal of sewage at Kimmel Bay. The Urban District Council of Abergele had under consideration proposals for a sewerage scheme to serve this area. He was making further inquiries with regard to these proposals.

Alleged Small-pox Case on Board Ship.—Mr. GROVES asked on November 18 for details of a case of small-pox recently found when a ship called at Gibraltar, the patient being an American doctor. Dr. ELLIOT replied that particulars of this case had been given to his Department, which indicated that the illness from which the patient suffered might not have been small-pox. The patient was successfully vaccinated against small-pox in childhood, and had been vaccinated on several subsequent occasions without result.

Post-vaccinal Encephalitis.—Dr. ELLIOT, replying to Mr. Groves on November 21, said that in the five cases of post-vaccinal encephalitis referred to in the Annual Report of the Chief Medical Officer for 1937 Government lymph had been used. Medical practitioners had been requested from time to time by notice in the medical press and otherwise to report to his department any case of acute nervous disease following within four weeks of vaccination. Information regarding such cases was also obtained from the returns rendered by public vaccinators to the Government Lymph Establishment regarding the use of Government lymph. There was no reason to suppose that any sensible number of such cases escaped the notice of the Department.

Tuberculosis Death Rate in Women.—Colonel COLVILLE told Mrs. Hardie, on November 22, that the report of the medical officer of health for Glasgow contained the statement that the death rate from tuberculosis among girls from 15 to 25 years of age had increased, and that notifications of this disease among this age group had risen during the last five years. While the general death rate from pulmonary tuberculosis had continued to decline, the relatively high mortality among young adults had been a matter of serious concern for many years. The rate among girls in Glasgow was receiving special consideration from the medical officer of health and his staff.

Chronic Incapacity of Insured Workers in Scotland.—On November 22 Colonel COLVILLE informed Mrs. Hardie that the clinical inquiry by the Department of Health for Scotland into the problem of chronic incapacity of insured workers in

Scotland was still proceeding. It was too early to give any indication of the conclusions which might be drawn. About 25,000 cases had now been reviewed, of which some 5,000 had undergone special clinical examination.

Storage of Blood for Transfusion.—Dr. ELLIOT said on November 24 that he knew the transfusion of stored blood had been extensively adopted in Spain during the war. His advisers were in touch with the arrangements for blood transfusion which are proposed in this country by the British Red Cross Society and the hospitals.
